BACK AMONG
FRIENDS

THORAZINE®

brand of

CHLORPROMAZINE

Tablets:
50 and 100 mg
of the HCl

Back among friends—an important source of much-needed support. She went into the hospital with a psychiatric emergency but left more like herself—delusions, hallucinations, and other psychotic target symptoms under control with 'Thorazine'. And 'Thorazine' maintenance can help keep her out of the hospital in the future.

From initial psychiatric emergency through maintenance treatment, 'Thorazine' offers effective antipsychotic therapy with 18 convenient dosage forms and strengths. This means you can precisely tailor dosage to individual patient needs—increasing or decreasing as the situation demands.

'Thorazine'. The most widely tested and highly flexible antipsychotic available today.

Helps return psychotic patients to reality

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase). For the treatment of severe behavior problems of combativeness, explosive hyperexcitability (which cannot be accounted for by immediate provocations) and in persistent hyperactivity in mentally retarded patients. (Not indicated in simple mental retardation.)

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: The possibility of extrapyramidal reactions from chlorpromazine may confuse the diagnosis of Reye's syndrome or other encephalopathy. Therefore, avoid use in children or adolescents with suspected Reye's syndrome.

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. Chlorpromazine is excreted in the breast milk of nursing mothers.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Patients with a history of hepatic encephalopathy due to cirrhosis have increased sensitivity to the C.N.S. effects of chlorpromazine. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Special monitoring of adverse effects in mentally retarded patients may be necessary due to verbal deficits of these patients. High-dose and/or long-term therapy may reduce learning performance in retarded patients. Antiemetic effect may mask signs of toxic drug overdosage or obscure diagnosis of conditions such as intestinal obstruction, brain tumor, and Reye's syndrome (see Warnings). Discontinue high-dose, long-term therapy gradually. Patients on therapy for more than six months, especially high-dose therapy, should be evaluated periodically for possible adjustment or discontinuance of drug therapy. In severely disturbed retarded patients, periodic discontinuation should likewise be tried (once or twice a year) to assess the effects on behavioral problems. 'Thorazine' tablets contain FD&C Yellow #5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. Although the overall incidence of FD&C Yellow #5 (tartrazine) sensitivity in the general population is low, it is frequently seen in patients who also have aspirin sensitivity. 'Thorazine' tablets are in the process of being reformulated to remove the FD&C Yellow #5. For specific information, contact Smith Kline &French Laboratories (outside Pa., call toll-free: 1-800-523-4835, ext. 4262; in Pa., call collect: 215-854-4262).

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only).

Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only).

Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg.

Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

PLAN AHEAD!

Order Your 1981 Appointment Books Now!!

The "week-at-a-glance" Appointment Book, published by the American Psychiatric Association, has been specifically developed to satisfy the needs of psychiatrists. It contains a comprehensive list of addresses and annual meeting dates of all major organizations and agencies of interest to psychiatrists. Members who have not tried this book in the past are urged to do so. It is returnable within 30 days for a full refund if not acceptable. (Returned copies must be received in saleable condition.)

The Pocket Size Appointment Book is also available and may be ordered in combination with the Desk Appointment Book.

Copies are available July 1980. Your order will be processed immediately upon receipt of coupon and payment.

DESK: $13.00
POCKET: $7.00
BOTH: $17.00

10% Discount for 10–99 copies
15% Discount for 100 copies or more

Send coupon to:

Publication Sales Department
American Psychiatric Association
1700 18th St., N.W., Washington, D.C. 20009

Please send me: ____ copies of **Desk Appointment Book** order #141 @ $13.00 ea.
____ copies of **Pocket Appointment Book** order #141-1 @ $7.00 ea.
____ copies of **Appointment Book Set** order #141-2 @ $17.00 ea.

____ To expedite my order, I am enclosing an additional $3.00 (U.S. only)

ENCLOSED IS MY TOTAL PAYMENT OF $ _____
(All domestic orders amounting to $35.00 or less must be accompanied by payment; all foreign orders, regardless of dollar amount, must be accompanied by payment. Orders over $35.00 will be invoiced with shipping/handling charges included.)

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, are not being considered for publication elsewhere, and have been approved by each author.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. Authors of accepted papers will be asked to sign the following statement:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. In such cases the following wording should be used:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

In addition, authors must obtain letters of permission from publishers for use of extensive quotations (more than 500 words) and of tables and figures that originally appeared elsewhere.

Patient Anonymity

Ethical as well as legal considerations require careful attention to the protection of a patient's anonymity in case reports and elsewhere. Identifying information such as names, initials, hospital numbers, and dates must be avoided. In addition, authors should disguise identifying information about a patient's characteristics and personal history.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 3–4 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by a cover letter indicating that the paper is intended for publication will not be reviewed until such a statement is received. On a separate sheet include the names and mailing addresses of any authors who are not members of APA; they will be sent a complimentary copy of the issue in which their article appears.

Authors will be notified as soon as possible of the receipt of their paper and the number assigned to it. **This number must be included in all further correspondence.** It is imperative that the corresponding author of submitted papers notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings, although not all papers can be published in the *Journal*. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in **final form,** i.e., are ready for review. Authors must **not** submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; **this number must appear in any further communications about the paper.**

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent **(no more than 15 double-spaced pages, including references, tables, and figures).** Brief Communications—2,500 words **(no more than 10 double-spaced pages, including references, tables, and figures).** Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures are used). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 7,500 words **(no more than 25 double-spaced pages—including tables and figures—and 100 references).** All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures, or references, etc. Single case reports should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and **no figures**) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular of Brief Communication length. (A "prompt publication policy" is automatically in effect for Clinical and Research Reports.) These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality and be of major immediate importance to the field. Authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. Because of space limitations not all letters can be printed. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed **double-spaced** throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review may be sent directly to the Book Review Editor, Nancy C. Andreasen, M.D., University of Iowa College of Medicine, 500 Newton Rd., Iowa City, Iowa 52240. Book reviews are usually solicited by the Book Review Editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Book Review Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer.

TYPING AND ARRANGING THE PAPER

All parts of the manuscript, including case reports, quotations, references, and tables, must be **double-spaced** throughout. All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) **nonerasable** bond paper. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Degrees (other than honorary or undergraduate degrees) should be included after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. Provide the department, institution, city, and state where the work was done. If multiple locations and authors were involved, indicate in parentheses which authors were affiliated with each institution. Provide a full address for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications. (No précis is used in the Clinical and Research Reports section.) The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are

both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material: a complete review of the literature is rarely desirable. **Accuracy of citation is the author's responsibility.** References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do **not** arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below, **double-spaced throughout** (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349-365, 1967
3. Jones AB: Long-term administration of tricyclic antidepressants: three-year follow-up. Am J Psychiatry (in press)
4. Smythe JCW (ed): Psychiatry and Human Values. Springfield, Ill, Charles C Thomas, 1971
5. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be **double-spaced** and no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise but descriptive title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3 1/4 inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information availabile in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit classroom or library reserve use by instructors and educational institutions, or of authors who wish to reprint their own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article.

Introducing...

Navane®
(thiothixene HCl) Intramuscular For Injection 5 mg/ml

new potency for rapid control of acute psychiatric emergencies

Now, Navane Intramuscular 5 mg per ml provides a more concentrate dosage form for rapid control of severely disturbed behavior associa ed with acute psychosis. Navane Intramuscular, in carefully monito ed doses, "...can produce significa improvement within hours and increase the accessibility of these [acutely disturbed] patients to mo gradual methods of pharmacologic treatment as well as to socio-envir mental intervention and psycho-therapy."[1]

Rapid tranquilization usually c be achieved without excessive seda tion.[1] Clinically significant hypoter sion, often seen with other injectab antipsychotic agents, is rare with Navane Intramuscular therapy.[1-3] I extrapyramidal symptoms occur, they are usually readily controlled by dosage adjustment or antiparki son agents.

ROERIG Pfizer

New York, New York 10017

For a brief summary of Navane prescribing information, including adverse reactions and contraindications, please see the following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml, 5 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml, 5 mg/ml

Contraindications. Navane (thiothixene) is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*– Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration of Navane to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children– The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration– As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution; Navane For Injection– Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane (thiothixene) Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate– In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Stimulants that may cause convulsions (e.g. picrotoxin or pentylenetetrazol) should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100, 1,000, and unit-dose pack of 100 (10 x 10's). Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100, 500, and unit-dose pack of 100 (10 x 10's).

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10 vials. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

Navane (thiothixene hydrochloride) Intramuscular For Injection is available in amber glass vials in packages of 10 vials. When reconstituted with 2.2 ml of Sterile Water for Injection, each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene, and 59.6 mg of mannitol. The reconstituted solution of Navane Intramuscular For Injection may be stored for 48 hours at room temperature before discarding.

CHARLES C THOMAS • PUBLISHER

New! IMPROVING EFFECTIVENESS AND REDUCING COSTS IN MENTAL HEALTH

By **Brian T. Yates,** *American Univ., Washington, D. C. Foreword by* **Frederick L. Newman.** Procedures for assessing, analyzing, and improving effectiveness, while reducing costs, for a wide variety of mental health delivery systems — residential treatment centers, private practice, clinics, community mental health centers, hotlines, addiction programs, correctional facilities — are featured in this book.

Following an introductory chapter on the fundamentals of cost-effectiveness analysis, the first of the book's two main sections delineates methods for assessing first the effectiveness and then the costs of specific mental health services. A subsequent chapter presents guidelines for measuring the relationship that exists between cost and effectiveness. Throughout the section, the author clarifies the assessment methods under discussion with examples from his own experience and explains how their application can contribute to the establishment of better mental health services.

The second section focuses on some of the more technical aspects of the subject; however, the material is presented in such a way as to be understandable to and usable by those with even the most basic of mathematical backgrounds. Explanations and numeric examples of linear programming, queuing, assignment, network, and probabilistic decision analyses are used to demonstrate that many common problems in mental health service provision can be effectively solved, including:

- selecting treatment and delivery systems for maximum effectiveness within budget constraints
- balancing client waiting costs against costs of employing more therapists
- discovering optimally effective or cost-effective matchings of clients and therapists

An exploration of future directions in cost-effectiveness analysis concludes the book. *'80, 204 pp., 31 il., 42 tables, $19.75*

New! **BURGLARY AND THEFT** *by* **John M. Macdonald.** Of special interest to psychiatrists will be the data on offender motivation, victim-offender relationships, victim reactions, and suspicious or delusional complainants. *'80, $19.75*

New! **THE HOUSEHOLD ENVIRONMENT AND CHRONIC ILLNESS: Guidelines for Constructing and Maintaining a Less Polluted Residence** *edited by* **Guy O. Pfeiffer** *and* **Casimir M. Nikel.** Discussion covers clinical manifestations of environmental chemical exposure, including advanced depression and related psychotic disorders. *'80, $13.75*

New! **TEENAGE PREGNANCY: Research Related to Clients and Services** *by* **Jean E. Bedger.** A decade of intensive research has resulted in this analysis of adolescent behavior, family attitudes, and counseling techniques used in working with pregnant teenagers. *'80, $16.75*

BASIC APPROACHES TO GROUP PSYCHOTHERAPY AND GROUP COUNSELING (2nd Ed., 3rd Ptg.) *edited by* **George M. Gazda.** Each approach is discussed with respect to definition, theoretical foundation, treatment goals and techniques, and limitations. *'79, $21.50*

THE EPILEPTIC IN HOME, SCHOOL AND SOCIETY: Coping with the Invisible Handicap *by* **Stephen W. Freeman.** Psychological, educational, psychosocial, vocational, legal, and medical aspects are explored. *'79, $14.75*

PEOPLE IN PAIN: A Guide to Pastoral Care *by* **James A. Vanderpool.** Case studies demonstrate effective pastoral counseling techniques for helping people suffering from neuroses, depression, alcoholism, and related concerns. *'79, $14.00*

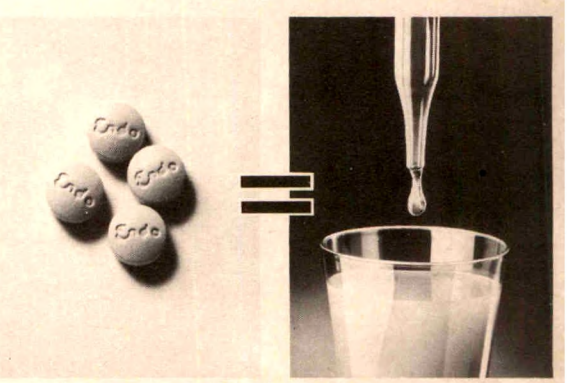
New
MOBAN®
molindone HCl
Concentrate
20 mg/ml
Easily administered
in fruit juice...has
a subtle cherry flavor
when taken alone



An effective antipsychotic agent with a favorable benefit/risk profile

NO incidence	excessive weight gain hepatotoxic changes ophthalmological changes persistent tardive dyskinesia skin pigmentation thyroid function changes tolerance development
LOW incidence	adverse drug interactions hematological changes hypotension nonpersistent symptoms of tardive dyskinesia sedation
MODERATE incidence	extrapyramidal reactions

This table compiled from clinical and field reports, according to the best available information.

For the schizophrenic patient

New MOBAN® molindone HCl Concentrate 20 mg/ml

four 25 mg tablets = 5 milliliters (100 mg)

Concentrated for maximum convenience of higher dosages...easy titration... enhanced compliance

Initial dosage with MOBAN®

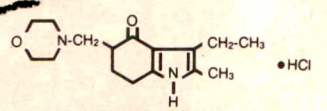
- usual starting dose is 50-75 mg/day
- may be increased to 100 mg/day in three to four days
- may be adjusted up or down according to response
- some patients with severe symptomatology may require an increase to 225 mg/day
- elderly and debilitated patients should be started on lower dosage

Please see next page for prescribing information.

Endo Laboratories DUPONT

A1

An effective antipsychotic agent



MOBAN® molindone HCl

New dosage form... Concentrate 20 mg/ml

continuing...Tablets 5 mg, 10 mg, 25 mg

DESCRIPTION MOBAN (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.8.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditioned response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN being excreted in urine and feces.

INDICATIONS MOBAN (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days no adverse effect
40 mg/kg/day—10 days no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days slight increase resorptions
40 mg/kg/day—10 days slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days no adverse effect
10 mg/kg/day—12 days no adverse effect
20 mg/kg/day—12 days no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

MOBAN has not been shown effective in the management of behavioral complications in patients with mental retardation.

PRECAUTIONS Some patients receiving MOBAN (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN. Caution should be exercised where increased activity may be harmful.

MOBAN does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, in humans convulsive seizures have been reported in a few instances.

EDO 854M580

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN (molindone hydrochloride) has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS—CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological—Extrapyramidal Reactions Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia Motor restlessness may occur early.

Parkinson Syndrome Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Galactorrhea and gynecomastia have been reported infrequently. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN.

Cardiovascular Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN.

Skin Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN usage alone.

MOBAN (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia Although rarely reported with MOBAN (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN (molindone hydrochloride) should be individualized.

Initial Dosage Schedule The usual starting dosage is 50-75 mg/day.
- —Increase to 100 mg/day in 3 or 4 days.
- —Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- —An increase to 225 mg/day may be required in patients with severe symptomatology.

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule
1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN (molindone hydrochloride) from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents, (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles with potencies and colors as follows:

100's and 1000's:
5 mg orange
10 mg lavender
25 mg light green

As a concentrate containing 20 mg molindone hydrochloride per ml in 4 oz. (120ml) bottles.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

The Practice of Psychotherapy

A Guide for the Beginning Therapist

By RICHARD C. U'REN, M.D.

This book is a guide for psychiatric residents and other beginning psychotherapists in the performance of psychotherapy. It shows the professional how to elicit the most favorable patient response, from the initial interview through the concluding therapeutic session.

CONTENTS: Introduction. PROCEDURES. First Meeting. Defining Problems. The Proceedings of Therapy. Problems in Therapy. Ending Therapy. WORKOUTS. Blue Woman. An Anxious Man. A Troubled Woman. A Proposition. A Diagnostic Predicament. Appendix: A Psychiatric Write-Up. Index.

1980, 192 pp., $19.50 ISBN: 0-8089-1242-9

Alcoholism: A Practical Treatment Guide

Edited by STANLEY E. GITLOW, M.D. and HERBERT S. PEYSER, M.D.

CONTENTS: *S. E. Gitlow*, An Overview. *L. Bissell*, Diagnosis and Recognition. *M. A. Block*, Motivating the Alcoholic Patient. *R. Baum and F. L. Iber*, Initial Treatment of the Alcoholic Patient. *D. H. Knott et al.*, After Detoxification—The Physician's Role in the Initial Treatment Phase of Alcoholism. *G. D. Shulman and R. D. O'Connor*, The Rehabilitation of the Alcoholic. *J. J. Zuska and J. A. Pursch*, Long-Term Management. *F. A. Seixas*, The Medical Complications of Alcoholism. *L. Hennecke and V. Fox*, The Woman with Alcoholism. *M. D. Feit*, Problems Peculiar to Low-Socioeconomic-Status Patients. *J. A. Knight*, The Family in the Crisis of Alcoholism. *H. S. Peyser*, The Role of the Psychiatrist, Psychologist, Social Worker, and Alcoholism Counselor. Appendices. *A*: Sedative-Hypnotic Drugs. *B*: National-Council-on-Alcoholism Criteria for the Diagnosis of Alcoholism. *C*: AMA Guidelines for Alcoholism: Diagnosis, Treatment, and Referral. *D*: *S. Psychosocial Disorders in General Practice

Edited by P. WILLIAMS and A. CLARE

As the level of interest in general practice psychiatry is high and a large body of research material is fast accumulating, the present is the ideal time for a critical appraisal of current achievements and an examination of future possibilities. This collection of twenty-three papers discusses questions raised by research such as: who should be referred to a psychiatrist? how much good psychiatric care can a general practitioner provide? in what way does the American system differ from the National Health Service? and in which direction should future emphasis be laid? The book provides a perspective for the realities and potential of primary health care in respect of the provision of an adequate and effective mental health care system.

Edition for the Americas published by Grune & Stratton.

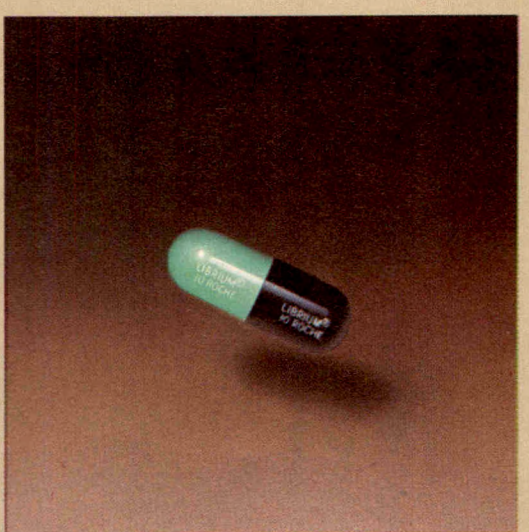
A legacy of evolution

Increasing evidence links anxiety to phylogenetically ancient brain structures.[1]

Catecholamine-rich locus coeruleus has been proposed as one of a number of anatomic structures intricately involved in anxiety.[2]



Specific brain binding sites for benzodiazepines appear to be evolutionary legacy shared by most vertebrate species studied.[3]

A legacy of excellence

Librium®

chlordiazepoxide HCl/Roche

5mg, 10mg, 25mg capsules

The origin of the species. Still a leader after 20 years.

Please see next page for summary of product information.

ROCHE®

Librium® 5mg, 10mg, 25mg capsules
chlordiazepoxide HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states. Efficacy beyond four months not established by systematic clinical studies. Periodic reassessment of therapy recommended.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Warn patients that mental and/or physical abilities required for tasks such as driving or operating machinery may be impaired, as may be mental alertness in children, and that concomitant use with alcohol or CNS depressants may have an additive effect. Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral–Adults:* Mild and moderate anxiety and tension, 5 or 10 mg *t.i.d.* or *q.i.d.*; severe states, 20 or 25 mg *t.i.d.* or *q.i.d. Geriatric patients:* 5 mg *b.i.d.* to *q.i.d.* (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) *Capsules*, 5 mg, 10 mg and 25 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10. Libritabs® (chlordiazepoxide) *Tablets*, 5 mg, 10 mg and 25 mg—bottles of 100 and 500. With respect to clinical activity, capsules and tablets are indistinguishable.

No two children are alike.
That is why
No two programs in Devereux
Are the same.

The Foundation's nationwide therapeutic programs vary considerably to serve the needs of children, adolescents and young adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Devereux also offers specialty programs:

- **Hedges Treatment Center** — For young people who are not ready to utilize a conventional residential treatment approach but whose problems do not warrant psychiatric hospital attention.
- **Center for Autistic and Schizophrenic Children** — A comprehensive treatment program for children under ten years of age.
- **Career House** — For intellectually bright high school graduating seniors and post-high school youth with problems of underachievement and/or personal adjustment.

WE'RE FIGHTING FOR YOUR LIFE

Unraveling
the mystery
of depression...
(Electron micrograph
of human synaptic cleft.*)
*Postulated site of tricyclic antidepressant activity

Current evidence suggests that many depressions have a biochemical basis in the form of a relative deficiency of neurotransmitters, such as norepinephrine and serotonin.

Deficiency of norepinephrine is postulated to be a major factor in a number of depressions. Laboratory studies have shown that desipramine is a potent inhibitor of norepinephrine re-uptake,[1] a mechanism of action that is thought to increase norepinephrine at the synaptic cleft when norepinephrine deficiency exists. (See Figures 1 and 2.)

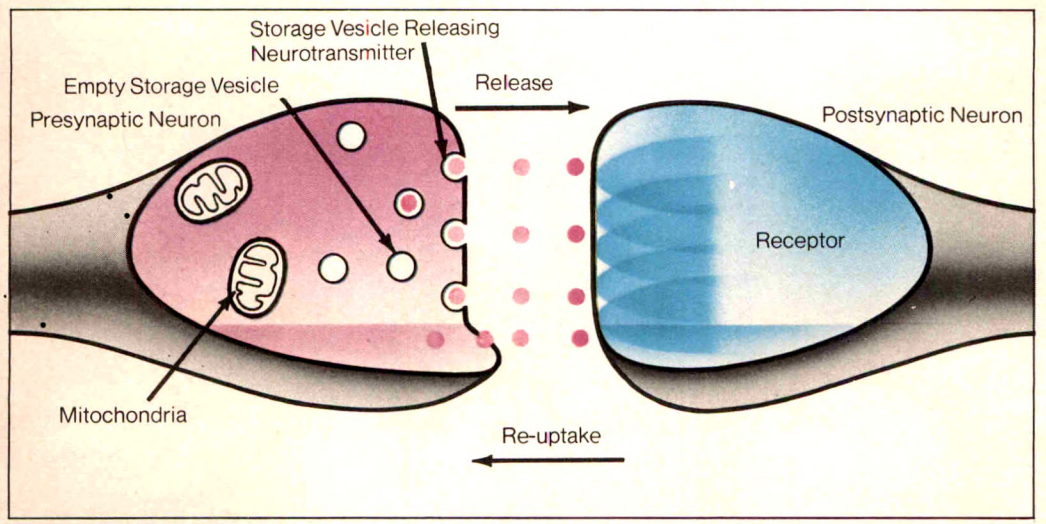

Figure 1. Diagrammatic representation of the *normal* process of neurotransmitter release, transfer across the synaptic cleft to the receptor site, and re-uptake. The supply of neurotransmitters is adequate in the normal state.

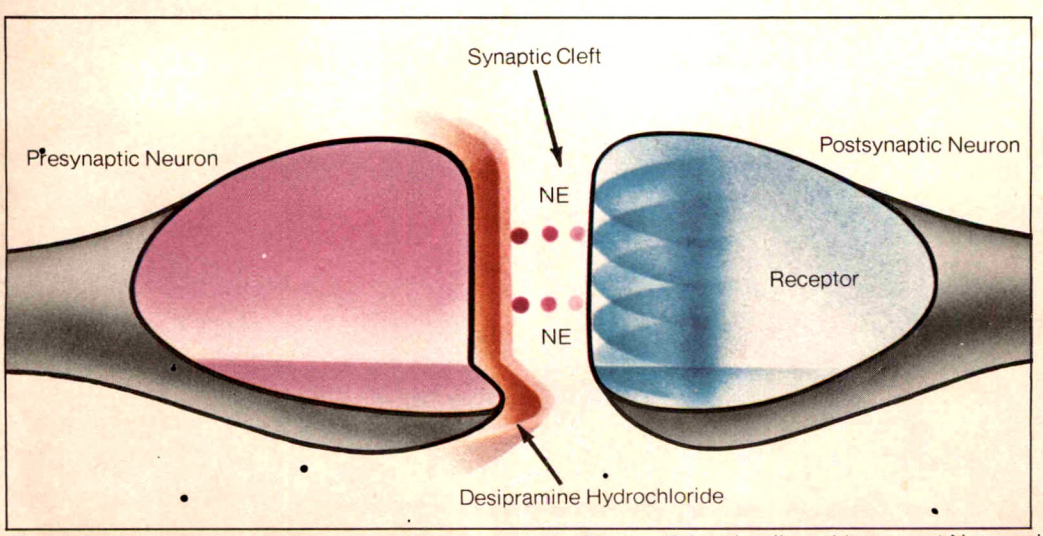

Figure 2. Diagrammatic representation of the mechanism of action of the tricyclic antidepressant Norpramin when there is a relative deficiency of the neurotransmitter norepinephrine (NE), as seen in some depressive states. Norpramin (desipramine hydrochloride) blocks the re-uptake of norepinephrine at the presynaptic nerve terminal (light brown band), ensuring increased cleft and receptor site neurotransmitter concentration.

Norpramin®
[desipramine hydrochloride tablets NF] 25,50,75,100,150 mg.

Potent blocker of norepinephrine re-uptake

According to current theory,[2,3] some depressions may respond to desipramine when other tricyclic antidepressants that block the re-uptake of a different neurotransmitter have been ineffective. Therefore, if your patient is unresponsive to treatment with one tricyclic, consider switching to a tricyclic that blocks the re-uptake of a different neurotransmitter.

Helps patient remain calm but active

Norpramin does not usually inhibit normal activity, although patients should be cautioned against driving or operating machinery if drowsiness occurs. (See Warnings, Precautions, and Adverse Reactions.)

Begins to improve sleep patterns within one week in some patients[4]

As the depression is relieved, difficulty in falling asleep, restlessness, and early morning awakening diminish.

Less anticholinergic activity

(See Warnings.)

Studies in the laboratory[5] and in normal human subjects[6,7] have shown that desipramine, with its single bond side chain, has less anticholinergic activity than amitriptyline or doxepin. This may mean:

- less dry mouth
- less blurred vision
- less urinary retention

See Following Page for Brief Summary of Prescribing Information.

Norpramin®
(desipramine hydrochloride tablets NF)

AVAILABLE ONLY ON PRESCRIPTION

Brief Summary

A maximum dosage of 300 mg. a day, as a single or divided dose, may now be prescribed for Norpramin. Since inadequate dosage is thought to be one of the major causes of treatment failure, the new therapeutic range should prove clinically helpful. Doses above 150 mg./day are not recommended for geriatric and adolescent patients.

MECHANISM OF ACTION: Available evidence suggests that many depressions have a biochemical basis in the form of a relative deficiency of neurotransmitters such as norepinephrine and serotonin. Norepinephrine deficiency may be associated with relatively low urinary 3-methoxy-4-hydroxyphenyl glycol (MHPG) levels, while serotonin deficiencies may be associated with low spinal fluid levels of 5-hydroxyindolacetic acid.

While the precise mechanism of action of the tricyclic antidepressants is unknown, a leading theory suggests that they restore normal levels of neurotransmitters by blocking the re-uptake of these substances from the synapse in the central nervous system.

Evidence indicates that the secondary amine tricyclic antidepressants, including Norpramin, may have greater activity in blocking the re-uptake of norepinephrine. Tertiary amine tricyclic antidepressants, such as amitriptyline, may have greater effect on serotonin re-uptake.

Norpramin (desipramine hydrochloride) is not a monoamine oxidase (MAO) inhibitor and does not act primarily as a central nervous system stimulant. It has been found in some studies to have a more rapid onset of action than imipramine. Earliest therapeutic effects may occasionally be seen in 2 to 5 days, but full treatment benefit usually requires 2 to 3 weeks to obtain.

INDICATIONS: Norpramin (desipramine hydrochloride) is indicated for relief of symptoms in various depressive syndromes, especially endogenous depression.

CONTRAINDICATIONS: Desipramine hydrochloride should not be given in conjunction with, or within 2 weeks of, treatment with an MAO inhibitor drug; hyperpyretic crises, severe convulsions, and death have occurred in patients taking MAO inhibitors and tricyclic antidepressants. When Norpramin (desipramine hydrochloride) is substituted for an MAO inhibitor, at least 2 weeks should elapse between treatments. Norpramin should then be started cautiously and should be increased gradually.

The drug is contraindicated in the acute recovery period following myocardial infarction. It should not be used in those who have shown prior hypersensitivity to the drug. Cross sensitivity between this and other dibenzazepines is a possibility.

WARNINGS: 1. Extreme caution should be used when this drug is given in the following situations: a. In patients with cardiovascular disease, because of the possibility of conduction defects, arrhythmias, tachycardias, strokes, and acute myocardial infarction. b. In patients with a history of urinary retention or glaucoma, because of the anticholinergic properties of the drug. c. In patients with thyroid disease or those taking thyroid medication, because of the possibility of cardiovascular toxicity, including arrhythmias. d. In patients with a history of seizure disorder, because this drug has been shown to lower the seizure threshold. **2.** This drug is capable of blocking the antihypertensive effect of guanethidine and similarly acting compounds. **3.** USE IN PREGNANCY: Safe use of desipramine hydrochloride during pregnancy and lactation has not been established; therefore, if it is to be given to pregnant patients, nursing mothers, or women of childbearing potential, the possible benefits must be weighed against the possible hazards to mother and child. Animal reproductive studies have been inconclusive. **4.** USE IN CHILDREN: Norpramin (desipramine hydrochloride) is not recommended for use in children since safety and effectiveness in the pediatric age group have not been established. **5.** The patient should be cautioned that this drug may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery. **6.** In patients who may use alcohol excessively, it should be borne in mind that the potentiation may increase the danger inherent in any suicide attempt or overdosage.

PRECAUTIONS: 1. It is important that this drug be dispensed in the least possible quantities to depressed outpatients, since suicide has been accomplished with this class of drug. Ordinary prudence requires that children not have access to this drug or to potent drugs of any kind; if possible this drug should be dispensed in containers with child-resistant safety closures. Storage of this drug in the home must be supervised responsibly. **2.** If serious adverse effects occur, dosage should be reduced or treatment should be altered. **3.** Norpramin (desipramine hydrochloride) therapy in patients with manic-depressive illness may induce a hypomanic state after the depressive phase terminates. **4.** The drug may cause exacerbation of psychosis in schizophrenic patients. **5.** Close supervision and careful adjustment of dosage are required when this drug is given concomitantly with anticholinergic or sympathomimetic drugs. **6.** Patients should be warned that while taking this drug their response to alcoholic beverages may be exaggerated. **7.** Clinical experience in the concurrent administration of ECT and antidepressant drugs is limited. Thus, if such treatment is essential, the possibility of increased risk relative to benefits should be considered. **8.** The sedative effects of Norpramin and benzodiazepines (*e.g.*, chlordiazepoxide or diazepam) are additive. Both the sedative and anticholinergic effects of the major tranquilizers are additive to those of Norpramin. **9.** This drug should be discontinued as soon as possible prior to elective surgery because of the possible cardiovascular effects. Hypertensive episodes have been observed during surgery in patients taking desipramine hydrochloride. **10.** Both elevation and lowering of blood sugar levels have been reported. **11.** Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression. **12.** Norpramin 25, 50, 75, and 100 mg. tablets contain FD&C Yellow No. 5 (tartrazine), which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. Although the overall incidence of FD&C Yellow No. 5 (tartrazine) sensitivity in the general population is low, it is frequently seen in patients who also have aspirin hypersensitivity.

ADVERSE REACTIONS: Note: Included in the following listing are a few adverse reactions that have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when Norpramin (desipramine hydrochloride) is given.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, arrhythmias, heart block, myocardial infarction, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic: numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns; tinnitus.

Anticholinergic: dry mouth, and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis, increased intraocular pressure; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (of face and tongue or general), drug fever, cross sensitivity with other tricyclic drugs.

Hematologic: bone marrow depressions including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: anorexia, nausea and vomiting, epigastric distress, peculiar taste, abdominal cramps, diarrhea, stomatitis, black tongue.

Endocrine: gynecomastia in the male, breast enlargement and galactorrhea in the female; increased or decreased libido, impotence, testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive), altered liver function; weight gain or loss; perspiration, flushing; urinary frequency, nocturia; parotid swelling; drowsiness, dizziness, weakness and fatigue, headache; alopecia.

Withdrawal Symptoms: Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

DOSAGE AND ADMINISTRATION: Not recommended for use in children. Lower dosages are recommended for elderly patients and adolescents. Lower dosages are also recommended for outpatients compared to hospitalized patients, who are closely supervised. Dosage should be initiated at a low level and increased according to clinical response and any evidence of intolerance. Following remission, maintenance medication may be required for a period of time and should be at the lowest dose that will maintain remission.

Usual Adult Dose: The usual adult dose is 100 to 200 mg. per day. In more severely ill patients, dosage may be further increased gradually to 300 mg./day if necessary. Dosages above 300 mg./day are not recommended.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response.

Treatment of patients requiring as much as 300 mg. should generally be initiated in hospitals, where regular visits by the physician, skilled nursing care, and frequent electrocardiograms (ECG's) are available.

The best available evidence of impending toxicity from very high doses of Norpramin is prolongation of the QRS or QT intervals on the ECG. Prolongation of the PR interval is also significant, but less closely correlated with plasma levels. Clinical symptoms of intolerance, especially drowsiness, dizziness, and postural hypotension, should also alert the physician to the need for reduction in dosage. Plasma desipramine measurement would constitute the optimal guide to dosage monitoring.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

Adolescent and Geriatric Dose: The usual adolescent and geriatric dose is 25 to 100 mg. daily.

Dosage should be initiated at a lower level and increased according to tolerance and clinical response to a usual maximum of 100 mg. daily. In more severely ill patients, dosage may be further increased to 150 mg./day. Doses above 150 mg./day are not recommended in these age groups.

Initial therapy may be administered in divided doses or a single daily dose.

Maintenance therapy may be given on a once-daily schedule for patient convenience and compliance.

OVERDOSAGE: See prescribing information for a discussion of symptoms and treatment of overdose.

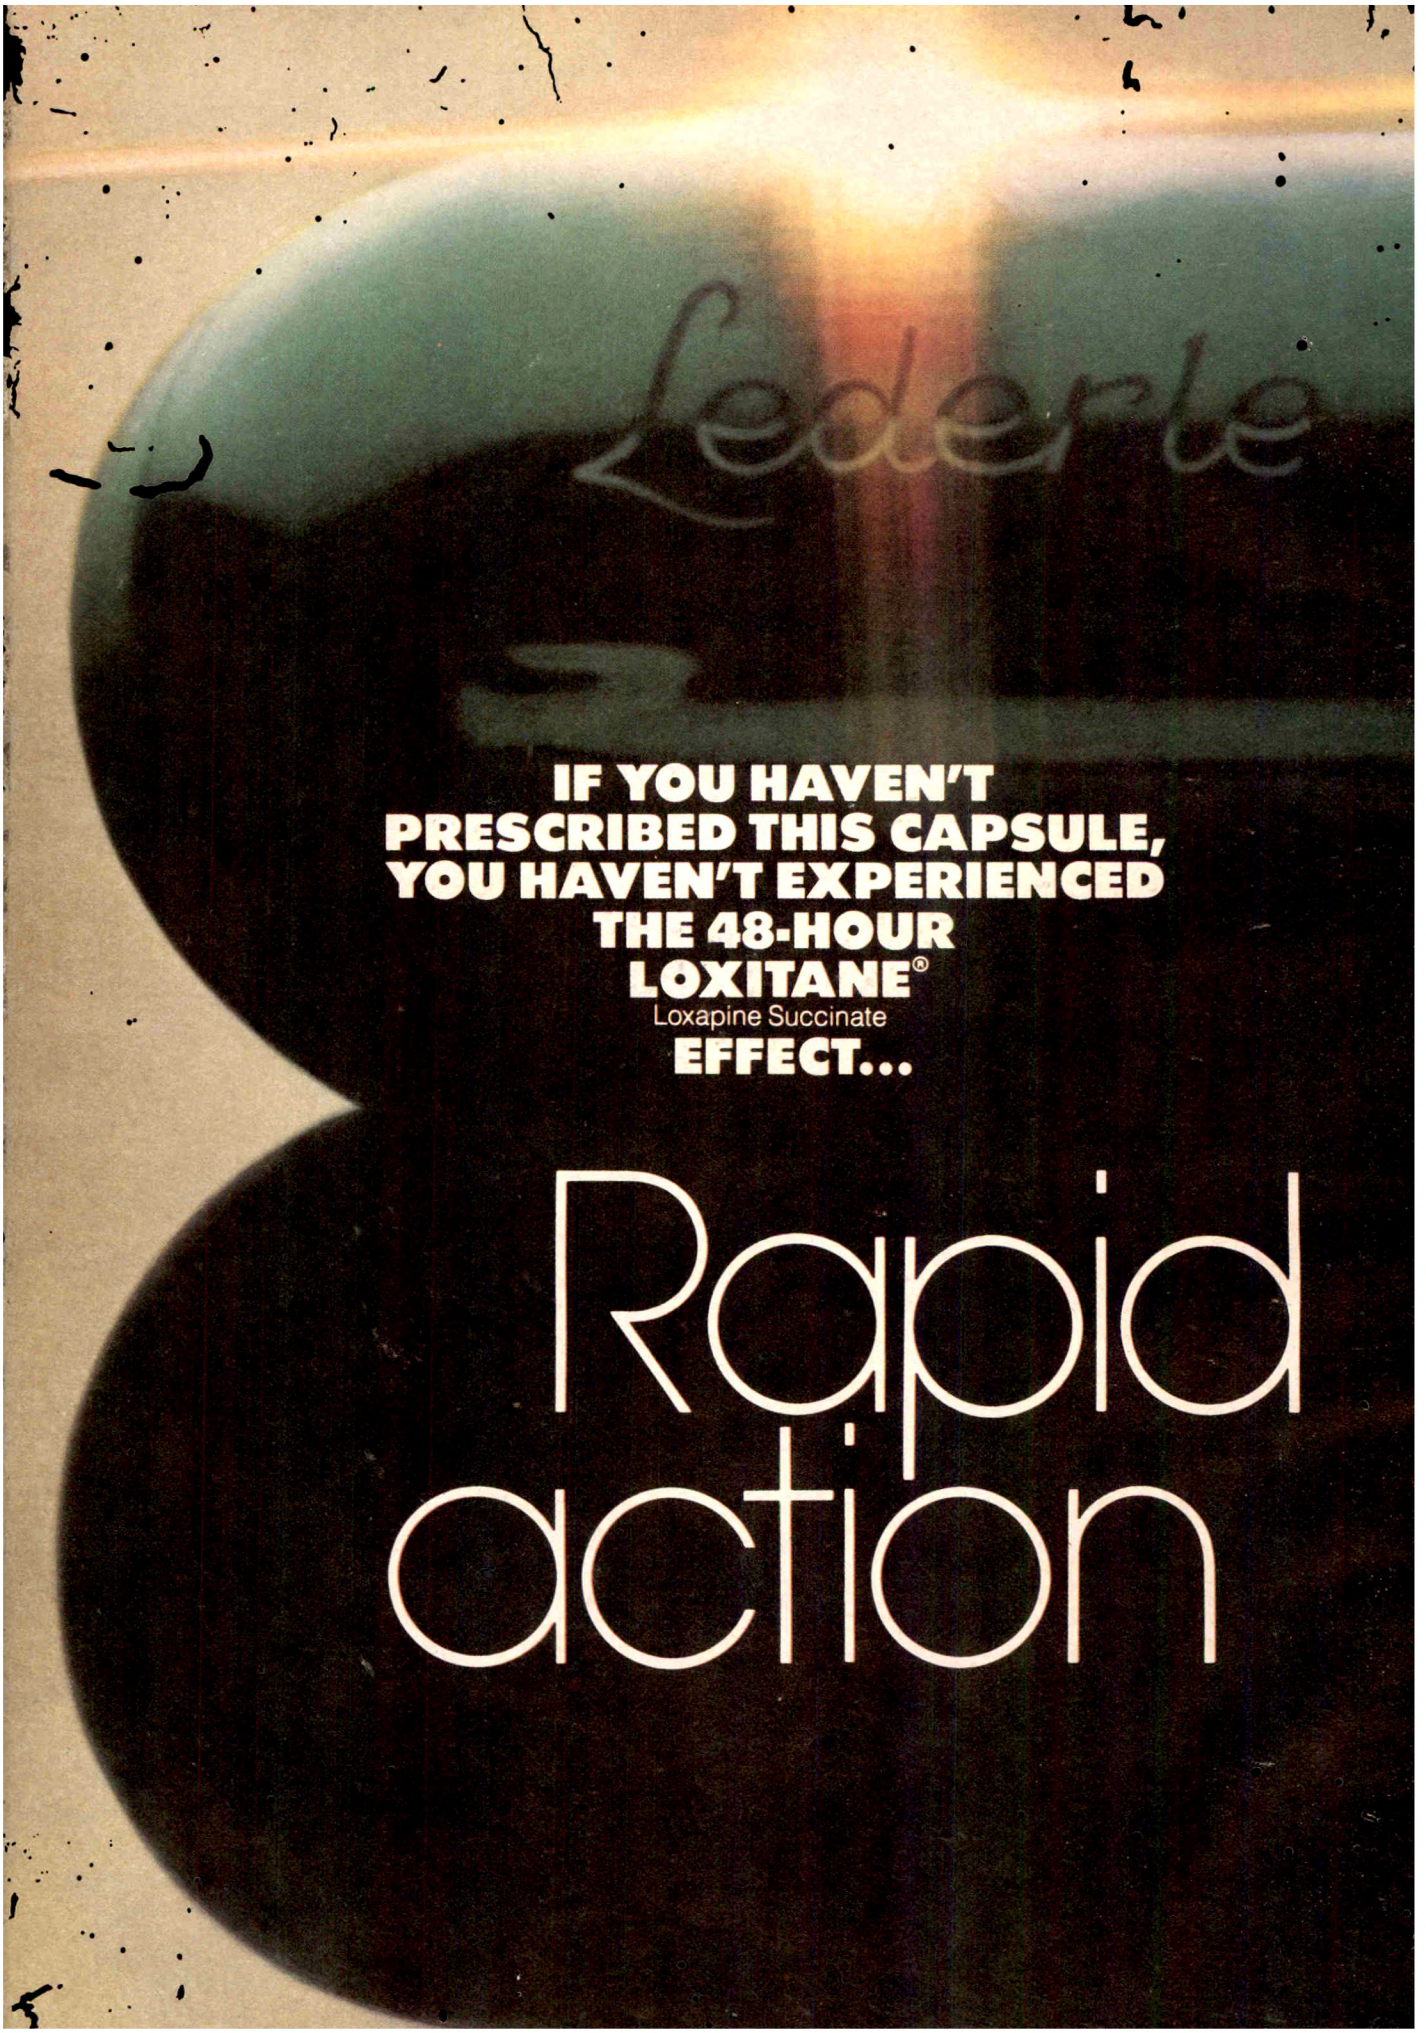
Protecting your Prescriptions

Recently, physicians—and, particularly, those new in private practice—are being approached by persons exhibiting varying extremes of drug-seeking behavior. Identifying these patients can become a problem; however, there are several clues which can alert you to the possibility that a patient may be a drug misuser/abuser:

- when an unfamiliar patient tells you that a controlled product he wants from you was previously prescribed for him by another physician (either in private practice or in a hospital) who is currently unavailable
- when an unfamiliar patient states that he is the patient of another physician for whom you may occasionally cover and wishes a prescription for a controlled product renewed

When either of these situations occurs, it is a good idea to ask the patient for the name of the physician or hospital and attempt to verify the story. If the patient tends to avoid answering your questions, it generally indicates a problem. Often with this type of patient, your prescription blank is the prime target. The following are some suggested guidelines to follow to insure its safety and proper use.



CUT OUT AND SAVE

The Well-Protected Prescription

GUIDELINES

1. Store all unused prescription pads in a safe place where they cannot be easily stolen
2. Minimize the number of pads in use at one time
3. Have prescription blanks numbered consecutively when printed so that you can tell if some sheets are missing
4. Never sign prescription blanks in advance
5. Write prescriptions in ink or indelible pencil to prevent changes
6. Write out the actual amount of medication prescribed in addition to using an Arabic or Roman numeral—this discourages alterations
7. Do not use your prescription blanks for writing notes or memos which can be erased and the blanks used again
8. Do not leave prescription pads in unattended examining rooms, office areas or in your bag or car where they can be easily picked up

Lederle
IF YOU HAVEN'T
PRESCRIBED THIS CAPSULE,
YOU HAVEN'T EXPERIENCED
THE 48-HOUR
LOXITANE®
Loxapine Succinate
EFFECT...
Rapid
action

25mg.

Impressive improvement in the often critical first two days In a series of clinical studies[1-4] involving hospitalized and ambulatory schizophrenics, there was a particularly impressive decrease in key target symptoms such as conceptual disorganization, thinking disorder, hallucinatory behavior, and anxiety-depression during the first two days. Particularly notable was an almost 40% mean symptomatic improvement in BPRS reported in 18 acute schizophrenic patients after 48 hours of treatment.[1] (See chart)

Steady progress facilitates earlier resocialization Throughout the early weeks of therapy, the LOXITANE difference continues to be apparent. In clinical trials, near maximal control has been reported[1-4] by week four and behavior patterns often approached normal. Mean overall symptom improvement of almost 96% in BPRS has been observed within 28 days.[1] Prompt therapeutic response permits approximate psychotherapy for a rapid return to more normal activities.

Symptom improvement in 18 acute schizophrenics on LOXITANE® Loxapine Succinate

Loxitane®
LOXAPINE SUCCINATE
Lederle

Recommended Daily Dosage

Dosage	Initially: 20-50 mg During first 24 hours: up to 100 mg Usual therapeutic level: 150 mg/day Maintenance: 60-100 mg/day Maximum: 250 mg/day Dosage may be divided as necessary. Reduced dosage in geriatrics and adolescents should be considered.

Brief Summary
LOXITANE® Loxapine Succinate Capsules
LOXITANE® C Loxapine Hydrochloride Oral Concentrate
INDICATIONS: Manifestations of schizophrenia.
CONTRAINDICATIONS: Comatose or severely depressed states; hypersensitivity to the drug
WARNINGS: Safe use during pregnancy or lactation has not been established; weigh potential benefits to possible hazards. Not recommended for use in children under 16. May impair mental and/or physical abilities especially during early therapy; warn ambulatory patients about activities requiring alertness and concomitant use of alcohol or other CNS depressants. Not recommended for management of behavioral complications in mentally retarded patients.
PRECAUTIONS: Use with extreme caution in patients with a history of convulsive disorders; use with caution in patients with cardiovascular disease or in those with glaucoma or a tendency to urinary retention particularly when on concomitant anticholinergic medication. Loxapine has an antiemetic effect in animals which might occur in man masking signs of overdosage of toxic drugs and obscuring intestinal obstruction or brain tumor. Since possible ocular toxicity cannot be excluded, observe carefully for pigmentary retinopathy and lenticular pigmentation.
ADVERSE REACTIONS: *CNS effects*, other than extrapyramidal, infrequent. Mild drowsiness may occur at beginning of therapy or upon dosage increase, usually subsides with continued therapy. Sedation, dizziness, faintness, staggering gait, muscle twitching, weakness and confusional states have been reported. Extrapyramidal reactions often occur early in treatment manifested by Parkinson-like symptoms (tremor, rigidity, excessive salivation, masked facies, akathisia) controllable by dosage reduction or antiparkinson drugs at usual dosages. Dystonic and dyskinetic reactions, while less frequently occurring, may be more severe, requiring dosage reduction or temporary withdrawal plus appropriate counteractive drugs. *Persistent Tardive Dyskinesia* may appear during prolonged therapy or following discontinuance, the risk greater in the elderly, especially females, on high dosage. Symptoms, persistent and in some patients apparently irreversible, are characterized by rhythmical involuntary movement of the tongue, face, mouth and jaw sometimes accompanied by involuntary movement of extremities. Since there is no known effective treatment, discontinue all antipsychotic drugs if symptoms appear. Reinstitution of treatment, increased dosage, or switching to another agent may mask syndrome. The syndrome may not develop if medication is stopped when fine vermicular movements of the tongue first appear. *Cardiovascular Effects:* Tachycardia, hypotension, hypertension, lightheadedness and syncope. ECG changes, not known to be related to loxapine use, have been reported. *Skin:* Dermatitis, edema of face, pruritus, seborrhea. Possible photosensitivity and/or phototoxicity; skin rashes of unknown etiology seen in a few patients in hot summer months. *Anticholinergic:* Dry mouth, nasal congestion, constipation, blurred vision (more likely to occur with concomitant use of antiparkinson agents). *Other:* Nausea, vomiting, weight gain or loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, polydipsia. Rarely, galactorrhea and menstrual irregularity of unknown etiology.

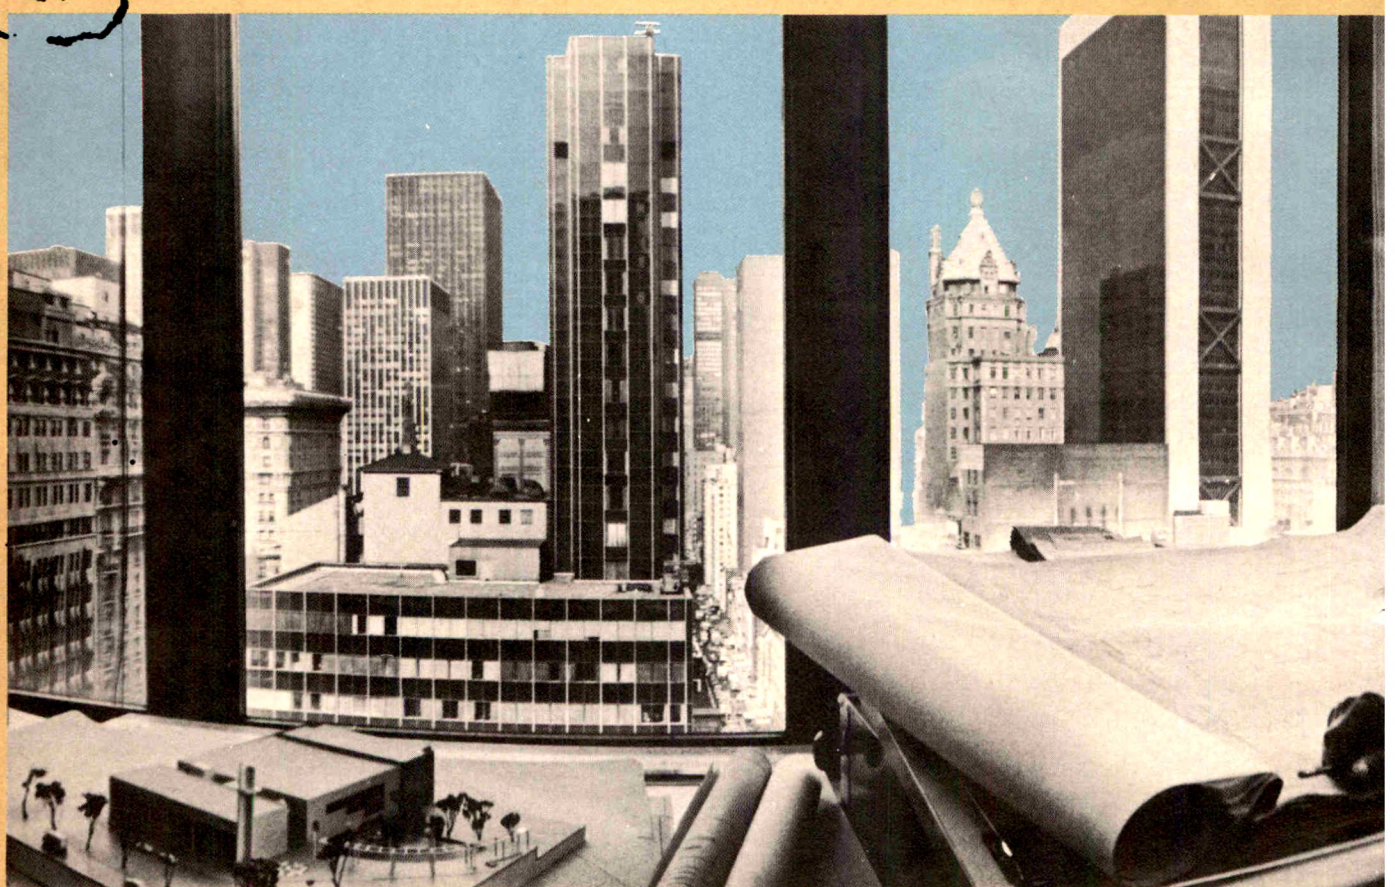
The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.



The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

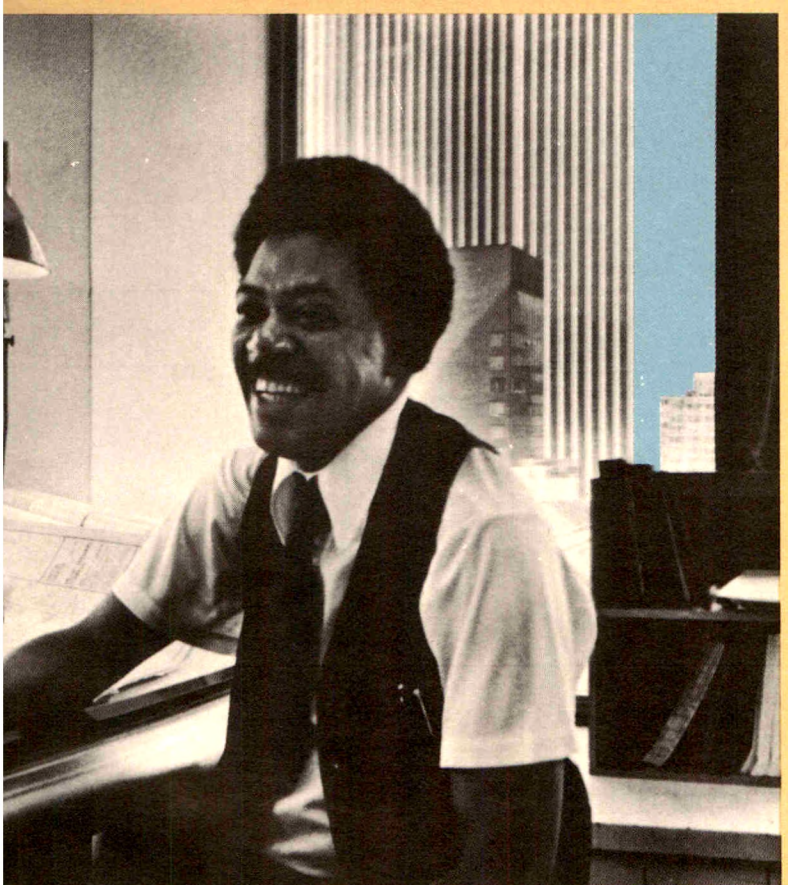
An equal opportunity employer. All our programs are accredited by the appropriate Councils of the Joint Commission on Accreditation of Hospitals.

7 OUT OF 10 NONPSYCHOTIC

The more logical choice for mixed depression and anxiety

☐ provides the well established antidepressant – amitriptyline – to relieve the depressive symptoms
☐ provides the action of Librium® (chlordiazepoxide HCl/ Roche)
- an antianxiety agent – not an antipsychotic – specific for the anxious symptoms
- a benzodiazepine with an outstanding safety record – not a phenothiazine

☐ achieves rapid relief and sustains it



The choice without phenothiazine drawbacks

Minimizes risk of tardive dyskinesia and other extrapyramidal side effects. The causal relationship between the phenothiazines and extrapyramidal side effects, including tardive dyskinesia, is well established. In contrast, the reported incidence of these adverse reactions with Limbitrol or either of its components is rare.

For a complete listing of side effects reported with Limbitrol, consult full disclosure.

ROCHE®

DEPRESSED PATIENTS ARE ALSO ANXIOUS...

In moderate depression and anxiety

What better reason to switch from a phenothiazine combination and start prescribing

Limbitrol® CIV

Tablets 5-12.5 each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt)
Tablets 10-25 each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt).

The nonphenothiazine formulation for the nonpsychotic patient

Please see summary of product information on following page.

LIMBITROL® TABLETS Tranquilizer—Antidepressant

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of moderate to severe depression associated with moderate to severe anxiety.

Contraindications: Known hypersensitivity to benzodiazepines or tricyclic antidepressants. Do not use with monoamine oxidase (MAO) inhibitors or within 14 days following discontinuation of MAO inhibitors since hyperpyretic crises, severe convulsions and deaths have occurred with concomitant use; then initiate cautiously, gradually increasing dosage until optimal response is achieved. Contraindicated during acute recovery phase following myocardial infarction.

Warnings: Use with great care in patients with history of urinary retention or angle-closure glaucoma. Severe constipation may occur in patients taking tricyclic antidepressants and anticholinergic-type drugs. Closely supervise cardiovascular patients. (Arrhythmias, sinus tachycardia and prolongation of conduction time reported with use of tricyclic antidepressants, especially high doses. Myocardial infarction and stroke reported with use of this class of drugs.) Caution patients about possible combined effects with alcohol and other CNS depressants and against hazardous occupations requiring complete mental alertness (e.g., operating machinery, driving).

Usage in Pregnancy: **Use of minor tranquilizers during the first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Since physical and psychological dependence to chlordiazepoxide have been reported rarely, use caution in administering Limbitrol to addiction-prone individuals or those who might increase dosage; withdrawal symptoms following discontinuation of either component alone have been reported (nausea, headache and malaise for amitriptyline; symptoms [including convulsions] similar to those of barbiturate withdrawal for chlordiazepoxide).

Precautions: Use with caution in patients with a history of seizures, in hyperthyroid patients or those on thyroid medication, and in patients with impaired renal or hepatic function. Because of the possibility of suicide in depressed patients, do not permit easy access to large quantities in these patients. Periodic liver function tests and blood counts are recommended during prolonged treatment. Amitriptyline component may block action of guanethidine or similar antihypertensives. Concomitant use with other psychotropic drugs has not been evaluated: sedative effects may be additive. Discontinue several days before surgery. Limit concomitant administration of ECT to essential treatment. See Warnings for precautions about pregnancy.

Limbitrol should not be taken during the nursing period. Not recommended in children under 12. In the elderly and debilitated, limit to smallest effective dosage to preclude ataxia, oversedation, confusion or anticholinergic effects.

Adverse Reactions: Most frequently reported are those associated with either component alone: drowsiness, dry mouth, constipation, blurred vision, dizziness and bloating. Less frequently occurring reactions include vivid dreams, impotence, tremor, confusion and nasal congestion. Many depressive symptoms including anorexia, fatigue, weakness, restlessness and lethargy have been reported as side effects of both Limbitrol and amitriptyline. Granulocytopenia, jaundice and hepatic dysfunction have been observed rarely.

The following list includes adverse reactions not reported with Limbitrol but requiring consideration because they have been reported with one or both components or closely related drugs:

Cardiovascular: Hypotension, hypertension, tachycardia, palpitations, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: Euphoria, apprehension, poor concentration, delusions, hallucinations, hypomania and increased or decreased libido.

Neurologic: Incoordination, ataxia, numbness, tingling and paresthesias of the extremities, extrapyramidal symptoms, syncope, changes in EEG patterns.

Anticholinergic: Disturbance of accommodation, paralytic ileus, urinary retention, dilatation of urinary tract.

Allergic: Skin rash, urticaria, photosensitization, edema of face and tongue, pruritus.

Hematologic: Bone marrow depression including agranulocytosis, eosinophilia, purpura, thrombocytopenia.

Gastrointestinal: Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, black tongue.

Endocrine: Testicular swelling and gynecomastia in the male, breast enlargement, galactorrhea and minor menstrual irregularities in the female and elevation and lowering of blood sugar levels.

Other: Headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, jaundice, alopecia, parotid swelling.

Overdosage: Immediately hospitalize patient suspected of having taken an overdose. Treatment is symptomatic and supportive. I.V. administration of 1 to 3 mg physostigmine salicylate has been reported to reverse the symptoms of amitriptyline poisoning. See complete product information for manifestation and treatment.

Dosage: Individualize according to symptom severity and patient response. Reduce to smallest effective dosage when satisfactory response is obtained. Larger portion of daily dose may be taken at bedtime. Single h.s. dose may suffice for some patients. Lower dosages are recommended for the elderly.

Limbitrol 10-25, initial dosage of three to four tablets daily in divided doses, increased up to six tablets or decreased to two tablets daily as required. Limbitrol 5-12.5, initial dosage of three to four tablets daily in divided doses, for patients who do not tolerate higher doses.

How Supplied: White, film-coated tablets, each containing 10 mg chlordiazepoxide and 25 mg amitriptyline (as the hydrochloride salt) and blue, film-coated tablets, each containing 5 mg chlordiazepoxide and 12.5 mg amitriptyline (as the hydrochloride salt) — bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50.

ROCHE®

ROCHE PRODUCTS INC.
Manati, Puerto Rico 00701

How to initiate and maintain therapy

Select dosage strength appropriate for each patient

- ☐ Limbitrol 5-12.5 is recommended to minimize drowsiness and for elderly patients
- ☐ Limbitrol 10-25 may be indicated for patients who tolerate medication without undue side effects

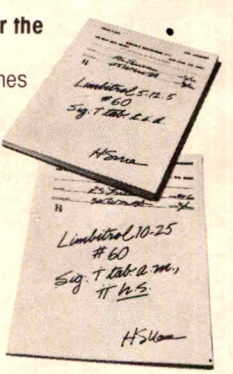
Specify daily dosage based on symptom severity

- ☐ An initial dosage of three tablets is recommended
- ☐ Dosage may be increased to six tablets or decreased to two tablets daily as necessary
- ☐ Once a satisfactory response is obtained, patients should be continued on the smallest dose required to maintain the desired effect

Utilize dosage options to best accommodate individual patient needs

- ☐ T.I.D. or Q.I.D., familiar regimens most suited for patients who tolerate medication without undue drowsiness
- ☐ Two tablets one hour before bedtime and one tablet midday may minimize daytime drowsiness and help relieve a common target symptom — insomnia
- ☐ Entire dosage h.s. to take maximum advantage of the sedative effect

Your guide to patient management... when you decide medication is needed



How to make each patient an informed patient

1. Discuss with patients the probability that they will experience drowsiness, especially during the first week.
2. Reassure your patients that drowsiness is one indication that the medication is working and that it may help alleviate their insomnia.
3. Encourage patients to report if drowsiness becomes troublesome so that, if necessary, dosage schedule can be adjusted.
4. Caution patients about the combined effects with alcohol or other CNS depressants. Let them know that the additive effects may produce a harmful level of sedation and CNS depression.
5. Caution patients about activities requiring complete mental alertness, such as operating machinery or driving a car.
6. Warn pregnant patients and patients of childbearing age that the safety of Limbitrol in pregnancy has not yet been established.

Please see complete product disclosure for other pertinent information.

Limbitrol should not be used under the following circumstances:

1. Hypersensitivity to benzodiazepines or tricyclic antidepressants.
2. Concomitantly with an MAO inhibitor. To replace an MAO inhibitor with Limbitrol, discontinue MAO inhibitor for a minimum of 14 days before cautiously initiating Limbitrol therapy.
3. During the acute recovery phase following myocardial infarction.

In moderate depression and anxiety

Limbitrol®

Relief without a phenothiazine

The American Psychiatric Association
Introduces

An essential program for clinicians learning to incorporate and utilize DSM-III

THE DSM-III INSTITUTIONAL INSTRUCTION KIT

THE DSM-III INSTITUTIONAL INSTRUCTION KIT acquaints physicians and their staff with:

- the multiaxial evaluation method used to report the official DSM-III diagnosis
- the use of new diagnostic categories in making a differential diagnosis
- the use of criteria as guides in making psychiatric diagnosis for the most significant disorders in:

Affective Disorders
Schizophrenia and Related Psychotic Disorders
Anxiety, Dissociative, and Somatoform Disorders
Personality Disorders
Disorders Usually Arising in Childhood or Adolescence

PROGRAM COMPONENTS:
The Instructor's Kit for workshop leaders contains:

- videotape of nine clinical case simulations
- loose-leaf binder containing:
  - — 4 audiocassettes plus transcripts of original faculty presentations
  - — 39 slides complementing audiotaped presentations
  - — course syllabus, patient histories, worksheets, references
  - — DSM-III diagnosis for each of 30 patient histories

The Participant's Kit for individual workshop members includes:

- course syllabus
- patient histories
- worksheets

CONTINUING MEDICAL EDUCATION (CME) CREDIT:
These learning materials can be used by educational organizations or institutions in the development of, or as an adjunct to, a variety of learning programs for CME Category 1, 2, or 5.

Brief Summary of Prescribing Information

Indications and Usage: Symptomatic relief of anxiety, tension, agitation, irritability ar insomnia associated with anxiety neuroses and transient situational disturbances; anxie associated with depressive symptoms and as a treatment of symptoms of anxiety if such sym toms are a significant feature of functional or organic disorders, particularly gastrointestinal cardiovascular.

Effectiveness in long-term use, i.e., more than 4 months, has not been assessed by systen atic clinical studies. Reassess periodically usefulness of the drug for the individual patient.

Contraindications: Known sensitivity to benzodiazepines or acute narrow-angle glaucoma.

Warnings: Not recommended in primary depressive disorders or psychoses: As with all CNS acting drugs, warn patients on lorazepam not to operate machinery or motor vehicles, and diminished tolerance for alcohol and other CNS depressants.

Physical and Psychological Dependence: Withdrawal symptoms like those noted with barb turates and alcohol have occurred following abrupt discontinuance of benzodiazepine (including convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Addic tion-prone individuals, e.g. drug addicts and alcoholics, should be under careful surveillanc when on benzodiazepines because of their predisposition to habituation and dependence Withdrawal symptoms have also been reported following abrupt discontinuance of benzod azepines taken continuously at therapeutic levels for several months.

Precautions: In depression accompanying anxiety, consider possibility for suicide.

For elderly or debilitated patients, initial daily dosage should not exceed 2mg to avoid ove sedation.

Terminate dosage gradually since abrupt withdrawal of any antianxiety agent may result i symptoms like those being treated: anxiety, agitation, irritability, tension, insomnia and occa sional convulsions.

Observe usual precautions with impaired renal or hepatic function.

Where gastrointestinal or cardiovascular disorders coexist with anxiety, note that lorazepar has not been shown of significant benefit in treating gastrointestinal or cardiovascular compo nent.

Esophageal dilation occurred in rats treated with lorazepam for more than 1 year a 6mg/kg/day. No effect dose was 1.25mg/kg/day (approximately 6 times the maximum huma therapeutic dose of 10mg/day). Effect was reversible only when treatment was withdrawn withi 2 months of first observation. Clinical significance is unknown; but use of lorazepam for pro longed periods and in geriatric patients requires caution and frequent monitoring for symptom of upper G.I. disease.

Safety and effectiveness in children under 12 years have not been established.

ESSENTIAL LABORATORY TESTS: Some patients have developed leukopenia; some have ha elevations of LDH. As with other benzodiazepines, periodic blood counts and liver function test are recommended during long-term therapy.

CLINICALLY SIGNIFICANT DRUG INTERACTIONS: Benzodiazepines produce CNS depressan effects when administered with such medications as barbiturates or alcohol.

CARCINOGENESIS AND MUTAGENESIS: No evidence of carcinogenic potential emerged i rats during an 18-month study. No studies regarding mutagenesis have been performed.

PREGNANCY: Reproductive studies were performed in mice, rats, and 2 strains of rabbits Occasional anomalies (reduction of tarsals, tibia, metatarsals, malrotated limbs, gastroschisis malformed skull and microphthalmia) were seen in drug-treated rabbits without relationship t dosage. Although all these anomalies were not present in the concurrent control group, they have been reported to occur randomly in historical controls. At 40mg/kg and higher, there was evidence of fetal resorption and increased fetal loss in rabbits which was not seen at lowe doses. Clinical significance of these findings is not known. However, increased risk of congeni tal malformations associated with use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during first trimester of pregnancy has been suggested in several studies Because use of these drugs is rarely a matter of urgency, use of lorazepam during this perioc should almost always be avoided. Possibility that a woman of child-bearing potential may be pregnant at institution of therapy should be considered. Advise patients if they become preg nant to communicate with their physician about desirability of discontinuing the drug.

In humans, blood levels from umbilical cord blood indicate placental transfer of lorazepam and its glucuronide.

NURSING MOTHERS: It is not known if oral lorazepam is excreted in human milk like other benzodiazepines. As a general rule, nursing should not be undertaken while on a drug since many drugs are excreted in milk.

Adverse Reactions, if they occur, are usually observed at beginning of therapy and generally disappear on continued medication or on decreasing dose. In a sample of about 3,500 anxious patients, most frequent adverse reaction is sedation (15.9%), followed by dizziness (6.9%), weakness (4.2%) and unsteadiness (3.4%). Less frequent are disorientation, depression, nausea, change in appetite, headache, sleep disturbance, agitation, dermatological symptoms, eye function disturbance, various gastrointestinal symptoms and autonomic manifestations. Incidence of sedation and unsteadiness increased with age. Small decreases in blood pressure have been noted but are not clinically significant, probably being related to relief of anxiety.

Overdosage: In management of overdosage with any drug, bear in mind that multiple agents may have been taken. Manifestations of overdosage include somnolence, confusion and coma. Induce vomiting and/or undertake gastric lavage followed by general supportive care, monitoring of vital signs and close observation. Hypotension, though unlikely, usually may be controlled with Levarterenol Bitartrate Injection U.S.P. Usefulness of dialysis has not been determined.

Ativan® (IV) for (lorazepam) Anxiety

Dosage: **Individualize for maximum beneficial effects. Increase dose gradually when needed, giving higher evening dose before increasing daytime doses. Anxiety, usually 2-3mg/day given b.i.d. or t.i.d.; dosage may vary from 1 to 10mg/day in divided doses. For elderly or debilitated, initially 1-2mg/day; insomnia due to anxiety or transient situational stress, 2-4mg h.s.**

How Supplied: **0.5, 1.0 and 2.0mg tablets.**

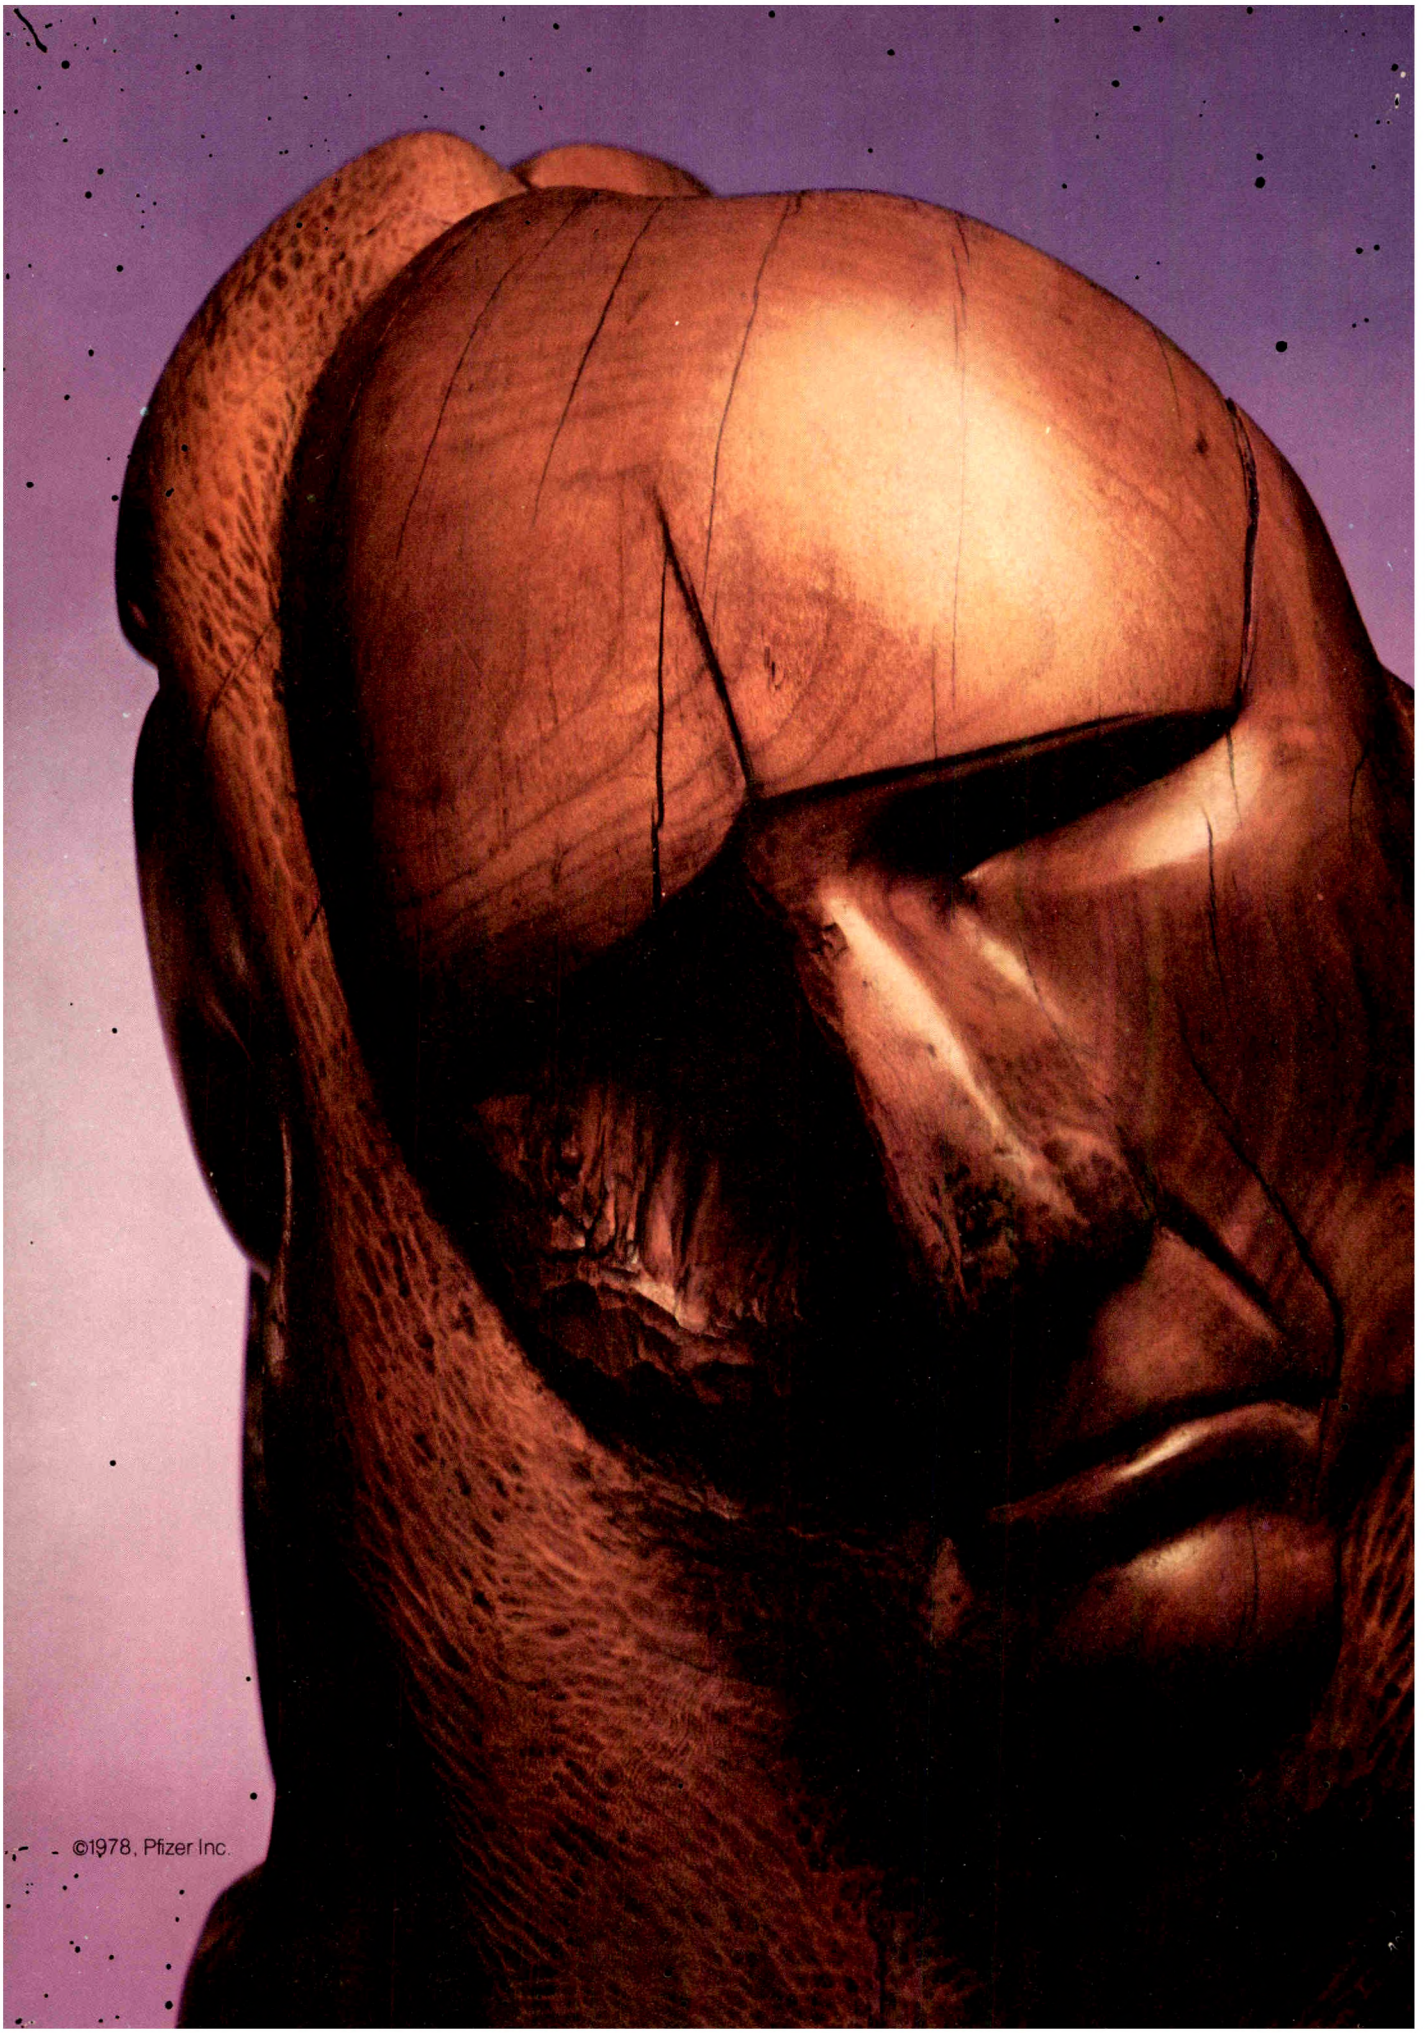
An age for anxiety.

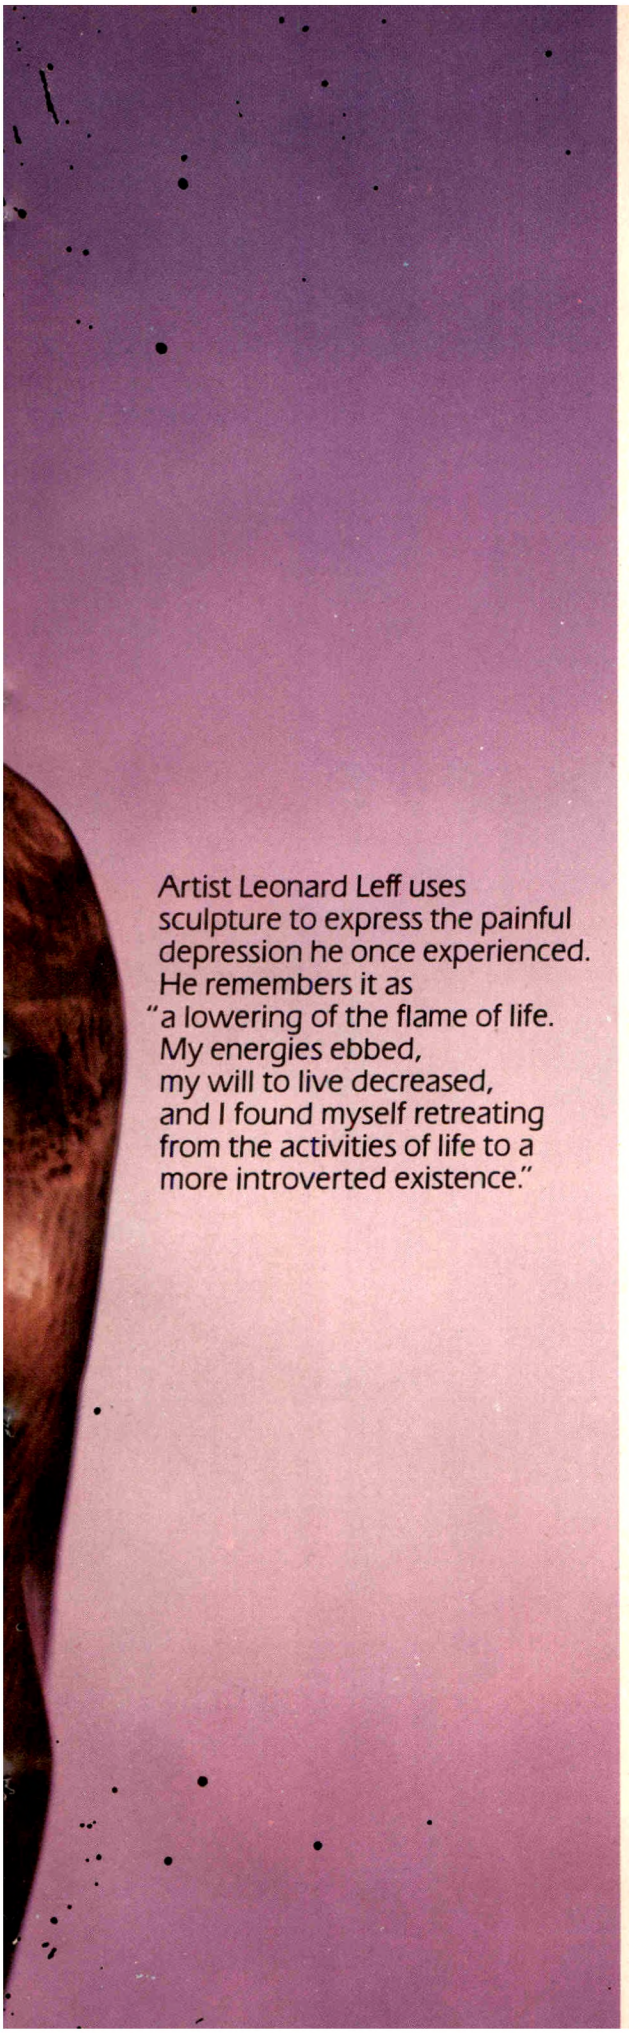
The aging process all too frequently is accompanied by anxiety states. When anxious older patients do not respond to your sympathetic counseling, a benzodiazepine may be the next logical step.

But which one? Here, more than in many other patient groups, the metabolites of the available compounds may make a decisive difference. Unlike diazepam, clorazepate and chlordiazepoxide, Ativan (lorazepam) has no long-acting metabolites, and its simple metabolism is less readily impaired with advancing age. Steady-state serum levels are rapidly achieved and disappear rapidly once you decide to discontinue therapy. For these reasons, residual effects are not likely to present problems. (The pharmacokinetic profile of a drug can define such characteristics as its absorption, distribution, metabolism and elimination but cannot, at present, be directly related to its therapeutic effectiveness.)

Proved effective in many nationwide, double-blind studies (including patients in older age groups), Ativan is compatible with a wide range of commonly prescribed drugs. (The benzodiazepines produce CNS depressant effects when administered with such medications as barbiturates or alcohol.) Patients who have trouble swallowing solid medication appreciate the small Ativan tablet, which is tasteless and disintegrates within seconds in water or fruit juice.



See important information on preceding page.



0.5 mg tablet

Ativan® (lorazepam) IV

for Anxiety

©1978, Pfizer Inc.

Artist Leonard Leff uses sculpture to express the painful depression he once experienced. He remembers it as "a lowering of the flame of life. My energies ebbed, my will to live decreased, and I found myself retreating from the activities of life to a more introverted existence."

WHEN DEPRESSION EXPRESSES ITSELF

SINEQUAN®
(DOXEPIN HCl)

ANTIDEPRESSANT EFFECTIVENESS with convenient once-a-day *h.s.* dosage*

150-MG CAPSULE†

Also available in:
100-mg, 75-mg, 50-mg, 25-mg, 10-mg CAPSULES and ORAL CONCENTRATE, 10 mg/ml, in 120-ml (4-oz) bottles

*The total daily dosage of Sinequan, up to 150 mg, may be administered on a once-a-day schedule without loss of effectiveness.

† The 150-mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

See Brief Summary on next page for information on contraindications, warnings, precautions and adverse reactions.

ANTIDEPRESSANT EFFECTIVENESS

SINEQUAN®
(DOXEPIN HCl)

150-mg CAPSULE*

CONVENIENT ONCE-A-DAY *h.s.* DOSAGE

which may improve patient compliance. The total daily dosage, up to 150 mg per day, may be given on a once-a-day schedule without loss of effectiveness. Sinequan may also be given on a divided dosage schedule, up to 300 mg per day.

PROMINENT SEDATIVE EFFECT

which may help to relieve the difficulty in falling and staying asleep, and the early-morning awakening often associated with depression.

ESTABLISHED ANTIANXIETY ACTIVITY

to help alleviate the anxiety which often accompanies clinical depression.

USUALLY WELL TOLERATED

At doses up to 150 mg per day, Sinequan does not generally affect the antihypertensive activity of guanethidine and related compounds. Tachycardia and hypotension have been reported occasionally. Drowsiness is the most commonly observed side effect. Dry mouth, blurred vision, constipation and urinary retention have been reported.

EXTENDED RANGE OF DOSAGE STRENGTHS

for flexibility in individualizing therapy.

*The 150-mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.

BRIEF SUMMARY
SINEQUAN® (doxepin HCl) Capsules/Oral Concentrate

Contraindications. Contraindicated in individuals who have shown hypersensitivity to the drug, and in patients with glaucoma or a tendency to urinary retention. These disorders should be ruled out, particularly in older patients. Possibility of cross sensitivity with other dibenzoxepines should be kept in mind.

Warnings. The once-a-day dosage regimen of SINEQUAN (doxepin HCl) in patients with intercurrent illness or patients taking other medications should be carefully adjusted. This is especially important in patients receiving other medications with anticholinergic effects.

Usage in Geriatrics: The use of SINEQUAN on a once-a-day dosage regimen in geriatric patients should be adjusted carefully based on the patient's condition.

Usage in Pregnancy: Reproduction studies performed in animals have shown no evidence of harm to the animal fetus. Since there is no experience in pregnant women receiving this drug, safety in pregnancy has not been established. There are no data with respect to the secretion of the drug in human milk and its effect on the nursing infant.

Usage in Children: Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

MAO Inhibitors: Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefore, MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug. The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time it has been administered and the dosage involved.

Usage with Alcohol: It should be borne in mind that alcohol ingestion may increase the danger inherent in any intentional or unintentional SINEQUAN overdosage. This is especially important in patients who may use alcohol excessively.

Precautions. Since drowsiness may occur with the use of this drug, patients should be warned of that possibility and cautioned against driving a car or operating dangerous machinery while taking this drug.

Patients should also be cautioned that their response to alcohol may be potentiated.

Since suicide is an inherent risk in any depressed patient, and may remain so until significant improvement has occurred, patients should be closely supervised during the early course of therapy. Prescriptions should be written for the smallest feasible amount.

Should increased symptoms of psychosis or shift to manic symptomatology occur, it may be necessary to reduce dosage or add a major tranquilizer to the dosage regimen.

Adverse Reactions. NOTE: Some of the adverse reactions noted below have not been specifically reported with SINEQUAN use. However, due to the close pharmacological similarities among the tricyclics, the reactions should be considered when prescribing SINEQUAN.

Anticholinergic Effects: Dry mouth, blurred vision, constipation, and urinary retention have been reported. If they do not subside with continued therapy, or become severe, it may be necessary to reduce the dosage.

Central Nervous System Effects: Drowsiness is the most commonly noticed side effect. This tends to disappear as therapy is continued. Other infrequently reported CNS side effects are confusion, disorientation, hallucinations, numbness, paresthesias, ataxia, and extrapyramidal symptoms and seizures.

Cardiovascular: Cardiovascular effects including hypotension and tachycardia have been reported occasionally.

Allergic: Skin rash, edema, photosensitization, and pruritus have occasionally occurred.

Hematologic: Eosinophilia has been reported in a few patients. There have been occasional reports of bone marrow depression manifesting as agranulocytosis, leukopenia, thrombocytopenia, and purpura.

Gastrointestinal: Nausea, vomiting, indigestion, taste disturbances, diarrhea, anorexia, and aphthous stomatitis have been reported. (See anticholinergic effects.)

Endocrine: Raised or lowered libido, testicular swelling, gynecomastia in males, enlargement of breasts and galactorrhea in the female, raising or lowering of blood sugar levels have been reported with tricyclic administration.

Other: Dizziness, tinnitus, weight gain, sweating, chills, fatigue, weakness, flushing, jaundice, alopecia, and headache have been occasionally observed as adverse effects.

Dosage and Administration. For most patients with illness of mild to moderate severity, a starting daily dose of 75 mg is recommended. Dosage may subsequently be increased or decreased at appropriate intervals and according to individual response. The usual optimum dose range is 75 mg/day to 150 mg/day.

In more severely ill patients higher doses may be required with subsequent gradual increase to 300 mg/day if necessary. Additional therapeutic effect is rarely to be obtained by exceeding a dose of 300 mg/day.

In patients with very mild symptomatology or emotional symptoms accompanying organic disease, lower doses may suffice. Some of these patients have been controlled on doses as low as 25-50 mg/day.

The total daily dosage of SINEQUAN (doxepin HCl) may be given on a divided or once-a-day dosage schedule. If the once-a-day schedule is employed the maximum recommended dose is 150 mg/day. This dose may be given at bedtime. **The 150 mg capsule strength is intended for maintenance therapy only and is not recommended for initiation of treatment.**

Antianxiety effect is apparent before the antidepressant effect. Optimal antidepressant effect may not be evident for two to three weeks.

Overdosage.

A. Signs and Symptoms

1. Mild: Drowsiness, stupor, blurred vision, excessive dryness of mouth.
2. Severe: Respiratory depression, hypotension, coma, convulsions, cardiac arrhythmias and tachycardias.

Also: urinary retention (bladder atony), decreased gastrointestinal motility (paralytic ileus), hyperthermia (or hypothermia), hypertension, dilated pupils, hyperactive reflexes.

B. Management and Treatment

1. Mild: Observation and supportive therapy is all that is usually necessary.
2. Severe: Medical management of severe SINEQUAN overdosage consists of aggressive supportive therapy. If the patient is conscious, gastric lavage, with appropriate precautions to prevent pulmonary aspiration, should be performed even though SINEQUAN is rapidly absorbed. The use of activated charcoal has been recommended, as has been continuous gastric lavage with saline for 24 hours or more. An adequate airway should be established in comatose patients and assisted ventilation used if necessary. EKG monitoring may be required for several days, since relapse after apparent recovery has been reported. Arrhythmias should be treated with the appropriate antiarrhythmic agent. It has been reported that many of the cardiovascular and CNS symptoms of tricyclic antidepressant poisoning in adults may be reversed by the slow intravenous administration of 1 mg to 3 mg of physostigmine salicylate. Because physostigmine is rapidly metabolized, the dosage should be repeated as required. Convulsions may respond to standard anticonvulsant therapy; however, barbiturates may potentiate any respiratory depression. Dialysis and forced diuresis generally are not of value in the management of overdosage due to high tissue and protein binding of SINEQUAN.

Supply. SINEQUAN is available as capsules containing doxepin HCl equivalent to: 10 mg, 75 mg, and 100 mg doxepin: bottles of 100, 1000, and unit-dose packages of 100 (10 x 10's). 25 mg and 50 mg doxepin: bottles of 100, 1000, 5000, and unit-dose packages of 100 (10 x 10's). 150 mg doxepin: bottles of 50, 500, and unit-dose packages of 100 (10 x 10's). SINEQUAN Oral Concentrate (10 mg/ml) is available in 120 ml bottles with an accompanying dropper calibrated at 5 mg, 10 mg, 15 mg, 20 mg, and 25 mg. Each ml contains doxepin HCl equivalent to 10 mg doxepin. Just prior to administration, SINEQUAN Oral Concentrate should be diluted with approximately 120 ml of water, whole or skimmed milk, or orange, grapefruit, tomato, prune or pineapple juice. SINEQUAN Oral Concentrate is not physically compatible with a number of carbonated beverages. For those patients requiring antidepressant therapy who are on methadone maintenance, SINEQUAN Oral Concentrate and methadone syrup can be mixed together with Gatorade®, lemonade, orange juice, sugar water, Tang®, or water; but not with grape juice. Preparation and storage of bulk dilutions is not recommended.

More detailed professional information available on request.

Pfizer **LABORATORIES DIVISION**
PFIZER INC.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient.

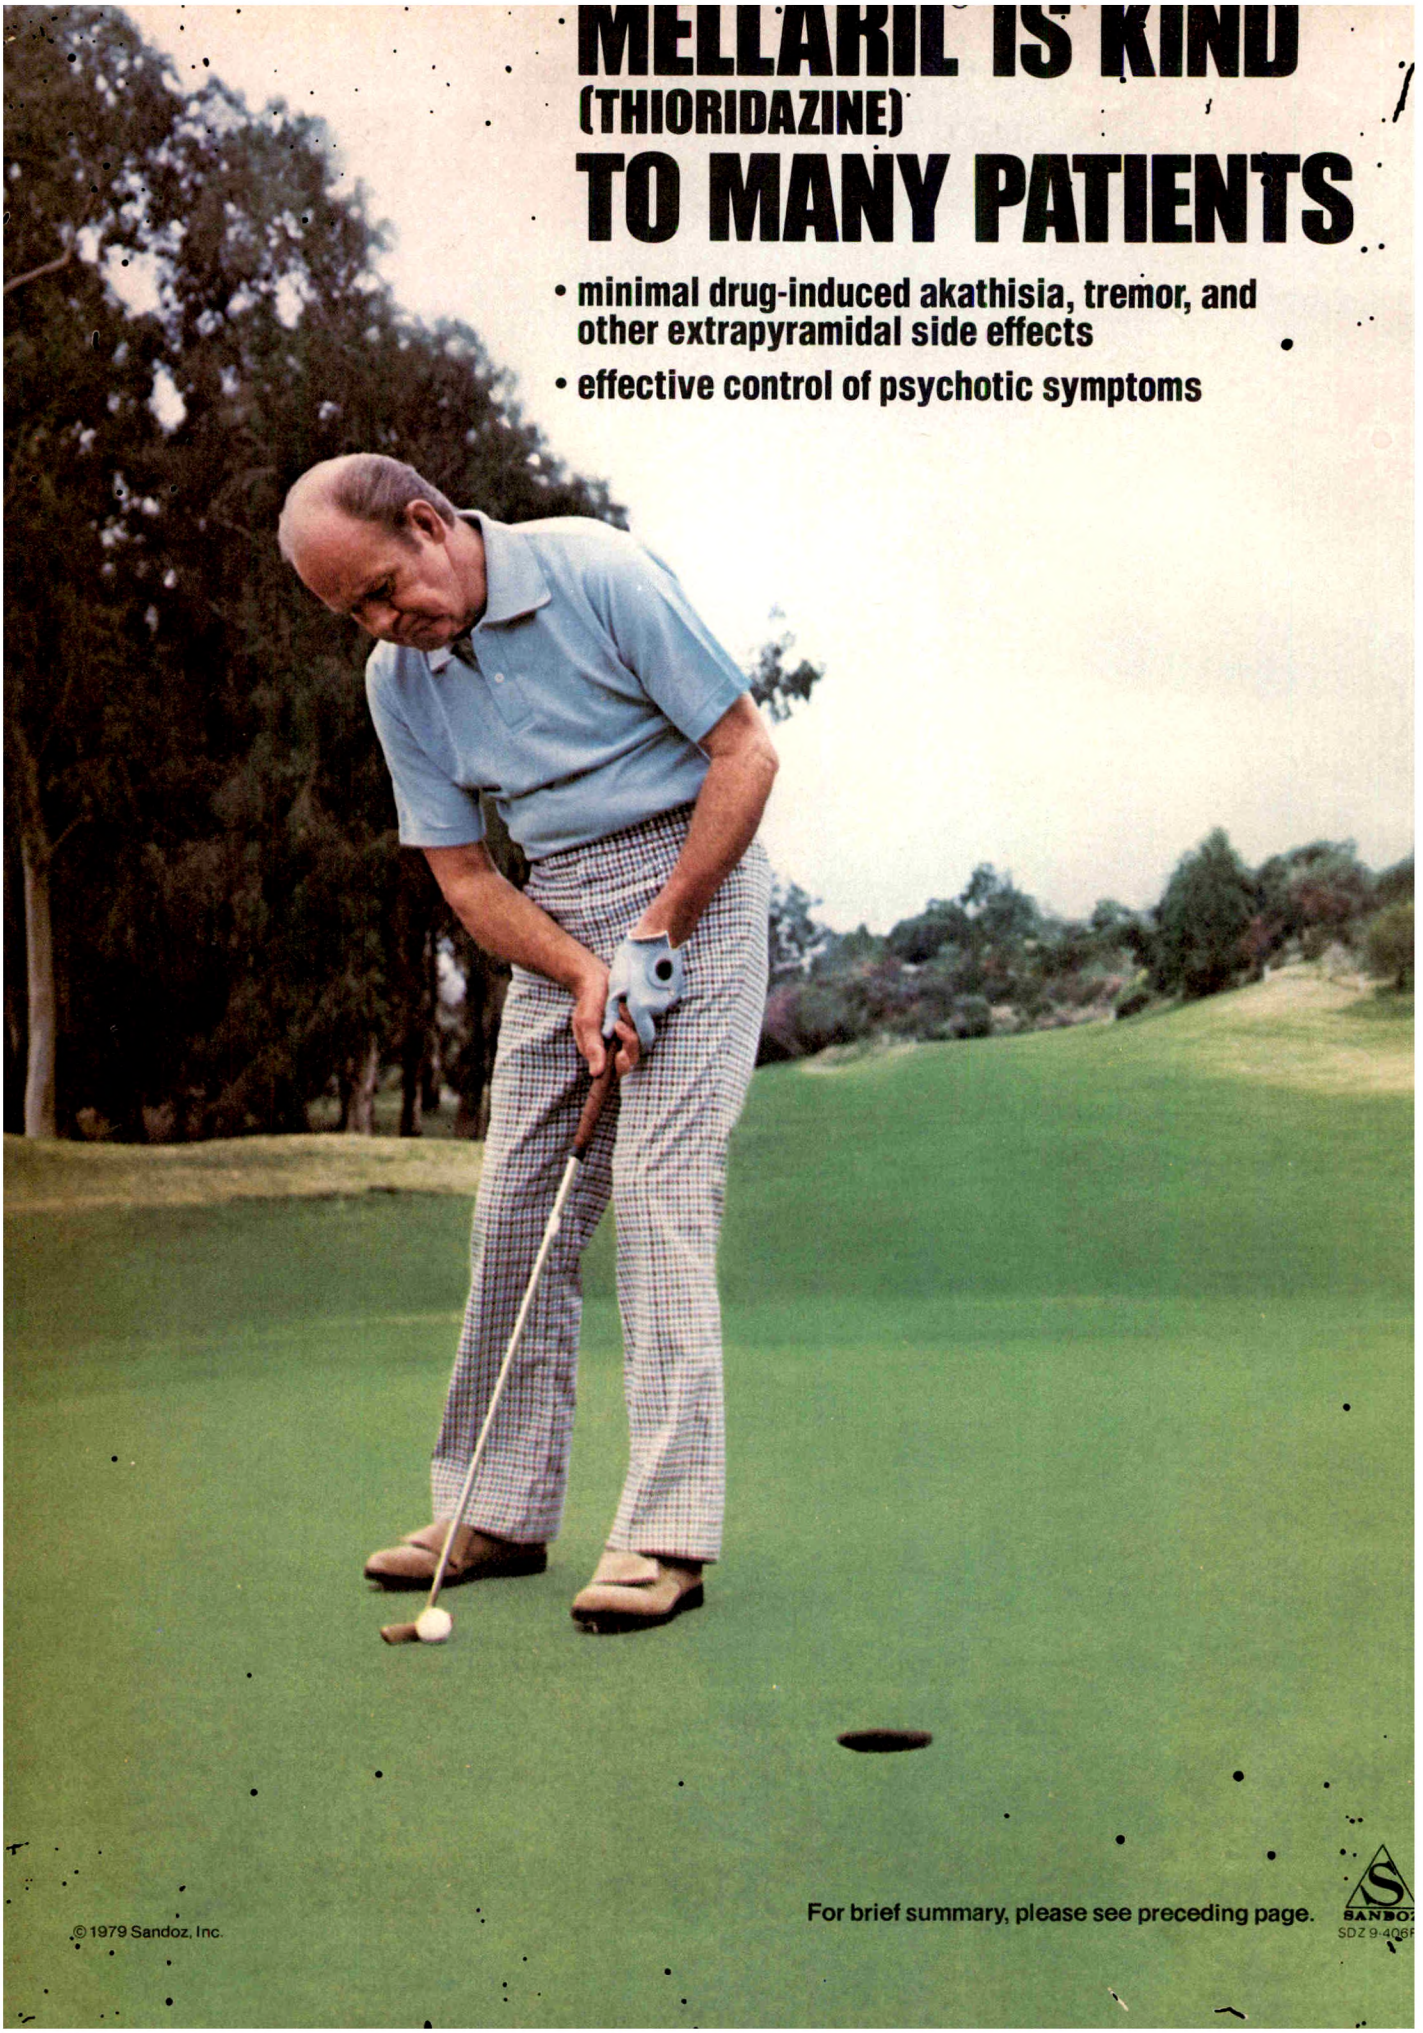
SANDOZ PHARMACEUTICALS. EAST HANOVER, NJ 07936

SANDOZ

SDZ 9-406R1

MELLARIL® IS KIND (THIORIDAZINE) TO MANY PATIENTS

- **minimal drug-induced akathisia, tremor, and other extrapyramidal side effects**
- **effective control of psychotic symptoms**



Mellaril® (thioridazine) is kind *two* ways to the patient with psychotic symptoms. It has an impressive record of relieving agitation, excitement, and hallucinations, while successfully helping the patient live and perform in the community. And, unlike other major tranquilizers, Mellaril (thioridazine) causes minimal akathisia or other extrapyramidal symptoms. Mellaril (thioridazine) is contraindicated in patients with hypertensive or hypotensive heart disease of extreme degree.

Effectiveness plus infrequent side effects—that's the kind of kindness the physician likes to see in a major tranquilizer!

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP

MELLARIL-S™ (thioridazine) SUSPENSION, per 5 ml (teaspoon): thioridazine base equivalent to 100 mg thioridazine HCl, USP

Trust-Based Therapy: A Contextual Approach

BY IVAN BOSZORMENYI-NAGY, M.D., AND BARBARA R. KRASNER, PH.D.

Contextual therapy has emerged from the practice of both individual and classical (transactional-systemic) family therapy. Its basic rationale is that the key dynamic of relationships is the trustworthiness that emerges from mutual consideration of all family members. Its contract maintains a simultaneous, multiple consideration of all the people affected by therapeutic intervention. Contextual therapy is not confined to any one model of practice, although it is founded on specific principles and methods. Its implications are obvious when applied to relationships, yet they are also evident in the aspects of individual approaches that are concerned with the therapist's liability and accountability. Although it encompasses the viable contributions of all schools of psychotherapy, contextual therapy operates out of its specific, ethically founded guidelines and strategies.

Contextual therapy has emerged out of our 45 combined years of psychotherapeutic experience, which includes intensive work with psychotic individuals, extensive experience with children, including the very young, and attempts at healing human suffering across all classes and layers of society (1). The contextual approach incorporates tenets of both individual therapy and classical (conjoint) family therapy, but its major contribution lies in the discovery that the key dynamic of relationships is merited trust. Acknowledging the concept of merited trust leads to a fundamentally new perspective of therapy: simultaneous multilateral consideration of more than one human being. Concern, trustworthiness, adversariness, exploitation, and fair mutuality between family members are heretofore neglected facets of therapy. This radical resource-oriented departure from the traditional (medical or psychological) individual perspective is hard to overemphasize.

For long-range effectiveness, we propose that the foremost therapeutic leverage lies in the processes of trust investments within the family and between family members and the therapist. Because family members are bound to each other by the ethical dimension of mutual trust, or lack of it, we also propose that a sufficiently responsible therapeutic contract is obliged to take account of all persons potentially affected by professional intervention (multidirectedness). Multidirectional accountability is also the key ingredient of therapeutic efficacy. It establishes the therapist's own trustworthiness and provides him or her with a rationale to help avoid the pitfalls of unilateral siding and of manipulation through countertransference. In our view, contextual therapy offers a strategic guideline that holds implications for all forms of psychotherapy.

The term "context" was chosen to indicate the dynamic connectedness of a person with his or her significant relationships. That is, while an individual is a discrete and unique biological entity, dynamically each person's life derives meaning through reference to a social context. Thus the word "context" is used to describe the long-term relational involvement of people, both in its systemic and multi-individual aspects, and includes four key dimensions: the factual, the psychological, the transactional, and the ethical (2). The ethical dimension may be illuminated most simply by the example of a mother who reliably cares for her baby. Her active concern becomes the source of her infant's trust, which, of course, eventually provides the rela-

tional and psychological foundations of his or her psychosocial development (3). By being caring, available, and accessible, functionally she helps her infant survive, develop, and function in the world. Her trustworthiness is also an ethical contribution. Whatever its comparative limitations, her mothering is a trustable reality based on personal investment and accumulates merit for her in the unique context of the parent-child relationship. The personal uniqueness of both parent and child is just as much a concern in the contextual view as are their transactional "systemic" roles.

In addition to its key dynamic of merited trust or "merit ledger" (reference 1, pp. 78, 371), context also refers to a person's relatedness to his or her multigenerational roots, with their specific racial, religious, and ethnic facets. The dynamic of merited trust was originally understood as interindividual in nature. In addition, however, having roots in common is transpersonal and can convey a legacy that is the result of expectations handed down from generation to generation. More than a theory, therapy based on trust resources is a pragmatic strategy that helps contextual therapists seize on evident signs of mistrust as potential resources for trust building.

A desired commodity, trust reduces the emotional cost of relational investment. This is illustrated by situations in which people cannot tolerate close relationships despite their desperate hunger for closeness. Trust is required as an initial investment in relationships, after which a person can take further steps toward trust building. It is also a necessity for being able to accept periods of transitory unfairness, a situation that is unavoidable in any relationship. A fluctuation of temporarily unilateral dependence, imposition, or even exploitation characterizes close relationships. Balance in relationships is kept through long-range multilaterality, which bridges and equilibrates short-term periods of unfairness and loss of trustworthiness.

ROOTS AND RELATIONSHIPS

The therapeutic significance of the life-long implications of legacy-bound (parent-child) relationships has been grossly disregarded by the traditions of both classical individual and classical family therapy, not to mention many symptom-oriented therapeutic fads. People stay tied to their families of origin long after it appears that family members have ended their connections with each other either by choice or perforce. Who lived for them, who wanted them, who was available to them, and who made material and relational investments in them are fundamental factors in their attitudes toward the world. Having roots and legacies in common is a nonsubstitutive bond among people that not only outlasts physical and geographical separations from families of origin but influences the degree to which offspring can be free to commit themselves to relationships outside of their original ties, including marriage and parenthood of their own. The long-term legacies of parental accountability and filial loyalty are inescapably weighty. A lack of interaction, negative affect, and even indifferent attitudes and abusive behavior may affect parent-child linkages but per se cannot devalue or terminate their importance. Even strong rebuke or revenge is usually meant to test a parent's or child's willingness to respond rather than to end the relationship. Procreation and roots-in-common invariably supersede the quality of the relation as the stimulus for continuity and mutual concern.

As prior investments in past and future generations, relational legacies are not only a part of a person's factual destiny but are an ethical claim. That is, receiving people are obliged to give. Expecting people are obliged to meet expectations. Over-available or over-performing relatives, for example, are entitled to acknowledgment of their investments and merits. In the first place, common roots, legacies, and linkages to racial, religious, ethnic, and familial contexts are nonsubstitutable configurations that contribute to an individual's uniqueness. In the second place, common bonds comprise a demand for balance in relationships. Merited trust born of mutual caring is the mainstay of such a balance.

Broader Implications of Intergenerational Legacies

Legacy-based therapeutic strategies are fundamentally different from psychological or transactional designs. As basic contextual determinants of relationships, legacies are created neither by emotional states nor by power alignments. If therapists are unable to base their convictions about the significance of legacies on their own relational experiences, they may well fall into the trap of the typical contemporary observer of human relationships: in this view repayment of obligations emanating from procreation is optional and depends on the participants' feelings and a variety of power manipulations. In subscribing to such a view, therapists surrender the major dimension of their therapeutic leverage.

Without entering into a debate on what constitutes deep versus superficial therapy, it can be said that an overt concern with relational responsibility almost instantaneously leads the therapist into depth dimensions of relationships. The question of relational responsibility is a private aspect of human life and is seldom faced even between partners themselves. Typically, discussion of the issue is either avoided and leads to isolation, to increasing relational (ethical) stagnation, pathogenicity, and untenability of relationships, or to painful and threatening confrontations. The contextual therapist is thus obliged to learn how to guide people through the most heated, direct, and controversial aspects of their relationship, that is, toward responsibility for trustworthiness. Contrary to its sur-

face appearance, the contextual approach is often short-term rather than long-term and direct rather than intellectualized or rationalistic.

TRUSTWORTHINESS AS A PROPERTY OF RELATIONSHIPS

The result of mutual consideration and actual exchange, trustworthiness is always a relational property of at least two people and cannot be reduced to the psychological universe of either one of them. Although it interlocks with the concept of basic trust as a psychological characteristic (3), trustworthiness always results from a mutilateral investment of relating partners on behalf of their mutual welfare and life interests. Trustworthiness is a characteristic of mature, nonexploitative (object) relations of any kind and, for example, determines whether an exciting love affair can be converted into an enduring marriage. It connects and channels the vicissitudes of the opposing needs of two or more persons in a relationship. Moreover, trustworthiness enables ego strength to be invested in controlling one's tendencies toward an exploitative misuse of close relationships and ultimately serves self-interest through maintaining the relational resource. Furthermore, caring for another person's needs can enhance personal satisfaction through empathy and love.

Retaining a trustworthy relationship is in the reality interest of all participants. A capacity for consideration and responsibility toward another person is thus to be viewed as neither an outgrowth of traditional guilt-based morality nor as a psychodynamic motive "located" in the superego. In practice, concentration on questions associated with the trustworthiness of close relationships incorporates and uses the therapeutic dimensions of individual-oriented psychotherapy like ego strength, reality testing, projections, and insight into distortions. Yet it also goes beyond them in pursuit of a balanced give and take in relationships. From the perspective of contextual therapy, the balance of give and take in relationships is a more sensitive and more accurate measure of reality distortions than is the insight-oriented self-reflection of one individual.

RESIDUAL TRUST AND FAMILY LEGACIES

In therapy the implications of transgenerational legacies are most readily visible in the "accounts" that exist in the reproductive aspects of parent-child relationships. The legacy of parental accountability originates from the existential fact of reproduction. Having given life to a dependent infant, parents owe it nurturance. Conversely, the legacy of filial loyalty originates from the fact of conception, early human survival, and growth. Children are linked to their parents by the event of birth; they are recipients of biological life, psychological endowment, nurturant care, and techniques for staying alive. Receiving life, benefits, skills, and guidance from their roots, the offspring are behooved to transmit them in kind to future generations. Moreover, it should be noted that in modified form the legacy of filial loyalty exists even when children have been given up or abandoned very early in life. Whatever the degree of parental responsibility or behavior after a child's birth, the child's relationship to the parents who gave him or her life is a unique, nonsubstitutable, and unreworkable fact of his or her existence. Even in cases of adoption, paradoxically perhaps, regard for the adoptive child's entitlement to his or her roots tends to improve the relationship with the adoptive parents.

Specifics of a given legacy shape the nature of both parental expectations and filial response to their expectations. For example, the sacrifice of a martyred family member can intensify the heirs' obligation to excel, or, marred by shame, the reputation of a family member can demand exoneration for generations to come. A case in point is the situation of the daughter of an alcoholic father. Bearing the weight of her father's former behavior and apparent failure, she may press her son toward perfection to make up for her filial shame. Overburdened by unfair legacy expectations, her son is faced with the unacceptable choices of abandoning his mother physically or emotionally or of submitting to her impossible demands. More realistically, contextual therapy offers him still another choice: he can help free himself and his mother for a new balance of trust and fairness in their relationship. Overcoming the mistrust, resentment, and stagnation that have accrued from his mother's undue substitutive and compensatory expectations of him, her son can find ways to discover aspects of his grandfather's behavior which serve to exonerate his life. Through active strategic work he can also determine and implement his own terms for accountably fulfilling his legacy rather than becoming entrapped into deferring to his mother's terms or simply learning to evade them.

MULTIDIRECTED PARTIALITY: GUIDELINE TO CONTEXTUAL THERAPY

Multidirected partiality (4), contextual therapy's basic methodology, is used to help the therapist guide clients toward a fresh assessment of legacy expectations and toward more interindividual fairness and trust. It assumes that sooner or later contextual therapists must be prepared to side with all family members, present or absent. It requires a therapist to hear and give courage to each family member as he or she struggles to bring to the surface his or her side. It is a process of consecutive siding with now one and now

the other relating partner in order to help family members state their respective terms with some confidence that opposing views can be heard and tolerated. Multidirected partiality is also meant to provide a paradigm that eventually can enable family members to listen and respond to one another's terms.

Multidirected partiality differs from the therapeutic stances of nonpartial neutrality on the one hand and stagnant unilateral partiality on the other. In our view, nonpartial neutrality is probably humanly impossible to attain, and traditional, individual-oriented therapy typically encourages fixed one-sidedness. Conversely, effectively employed, multidirected partiality begins a constructive process of trust building. It also requires that the therapist have the courage to side temporarily against family members as well as with them. It should be noted that consecutive siding with relating partners is a protection against the dangers of countertransference reactions.

Here a distinction should be made between the strategy of multidirected partiality and relational multilaterality, which is an inherently basic aspect of relationships. Multilaterality means that any action or transaction has at least two sides. In ethical terms it means that usually each of the two partners tends to approach the relationship with a self-centered viewpoint. The degree of fairness in a relationship is determined by the relative consideration each partner accords the other. Since neither only one party nor only an outsider can explore the relative merit accounts between them, the partners should be helped to explore and define their own mutual terms for fairness. For example, in case of adoption the adoptive parents should determine the terms of their own vulnerabilities and requirements for consideration but in the long run it should be the adopted child who determines his own terms of needs and entitlements. The therapist's role is to elicit the family members' active search for a definition and then assertion of their respective terms rather than to inject his or her own moral or behavorial value preferences. By offering consecutive multidirected partiality the therapist encourages family members to explore their own multilaterality. However, the therapist is not a contextually rooted participant in the family members' multilateral relationships. He or she is a natural partner only to the multilaterality of his or her own relationships, e.g., with his or her spouse, children, parents, and others of significance.

Identifying Trust in Stagnant Relationships

The following excerpt demonstrates a contextual process examination of trustworthiness among three family members who are stuck in their relationships with each other (stagnation). What begins as an initial diagnosis of an adolescent turns into a relational exploration of multi-individual diagnoses. The clinical material was obtained by way of a multidirected contract through which the therapist became accountable to all family members who in turn were helped to be accountable to each other. The multidirected therapeutic contract would have been in force whether or not all family members were present at the session.

Bob, a 16-year-old adopted, only son of a middle-class couple, was hospitalized after his second suicide attempt. In the evaluation interview Bob's father took a long time enumerating Bob's many doings: school failure, drug involvements, disrespectful behavior, and so forth. As a first attempt at developing trust resources, without disconfirming the validity of the father's concerns, the interviewer asked whether the parents could recall any instance in which Bob offered a helpful, concerned, or caring attitude to them. The mother denied that this had ever happened. The absurd intensity of her response could be taken as evidence of pathological scapegoating on the mother's part. However, the contextual therapist began to wonder about the possible merits on her side. How could he find aspects of her that would justify his contracting with her with genuine partiality? At this moment she was probably close to a point where she could describe the difficulties of her own childhood. The therapist envisaged that she might be manifesting a desperate overreaction to the fact that Bob's growth would soon lead to her loss of his regular companionship. Consequently, the therapist tried to elicit trust through exploring other aspects of Bob's merit, partly to be able to contract with him, partly to give the parents an opportunity to acknowledge his victimization, and ultimately to find new ways for Bob to display filial loyalty.

At another level of concern, the therapist asked Bob about his feelings concerning adoption. Bob responded that he would like to meet his natural mother but could not conceive of doing something that "brutal" to her. By this time the therapist had factual evidence of Bob's capacity for consideration, especially when Bob added that he did not want to hurt his adoptive parents, either. The merit of the victim becomes immediately obvious: he holds responsibility for not hurting the adult world that betrayed him at the beginning of his life.

From here on engagement in issues of trustworthiness became unavoidable and led directly into the therapist's curiosity about the parents' victimization in their own childhood. The movement from stagnation toward trust building had begun.

In this evaluation and assessment, the contextual therapist initially aimed at exploring the relational context of Bob's motivation to commit suicide. In fact, Bob spontaneously responded to the therapist's questioning by linking his self-destructive inclinations to his adoptive mother's habitual and overt disconfirmation of all his accrued merit as a loving son. In response to Bob's disclosures, the therapist pointed out the young man's concerns for both his natural and adoptive parents. Furthermore, he pointed out that it behooved Bob's parents to acknowledge their son's caring and consideration, which reflected favorably on them as well. At this moment Bob was able to say how much he loved his adoptive parents. With this, his mother started to cry and walked out of the room. Sub-

sequently his father was able to reveal that when he was away on business trips, Bob offered his mother comfort in her sadness and anxiety. This acknowledgment gave the therapist an opportunity to be partial to Bob while also endorsing the father's fairness. Obviously, blame was directed at the mother at this point, and even when she returned to the room she still was unable to acknowledge Bob's personal availability. This instance of extreme mistrust presented an opportunity to encourage her to describe the pain of her own childhood experiences. This, in turn, enabled the therapist to be genuinely partial to her as a victim of the past who presently appeared to be a victimizer.

The father's acknowledgment of Bob's active investment in his parents' well-being marked the beginning of strongly directive therapeutic explorations whose goals included 1) beginning to face intermember fairness and legacies, 2) reducing unfair legacy expectations by acknowledging them and redesigning repayment, 3) correcting one-sided, sometimes distorted, always unaddressed views of each other among family members, and 4) rebalancing the give and take among family members. In a brief time all of the family members had taken initial steps toward personal accountability for responsible action. As trust and trustworthiness began their upward spiral, new chances for positive collaboration and balanced relational growth among family members were likely to occur.

By the end of the initial session the family's concern for each other's well-being began to materialize in the midst of resentment, fears, and accusations. By being prodded to consider the merit as well as the pathology in his or her relationships, in some measure each person could begin to rethink his or her options. The therapist's concern about multidirectionality encouraged each of them to raise his or her side within the hearing of the others, and because they could be heard on their own terms each person was more willing to overcome his or her resistance to listening to the terms of others. After they were helped to voice both satisfactions and disappointments over the quality of their relationships, they could become somewhat freer to dwell on their own parts in contributing to unfair relating. By grasping the notion of joint responsibility for the modes of behavior among them each person was more able to examine interindividual sources of chronic mistrust. All the family members began to comprehend that each of them had made an investment in the welfare of the others and that to be productive these investments needed to be recognized and affirmed rather than discredited or negated. Moreover, no one had been designated as a scapegoat for the situation, and the session had taken place without condemning Bob's parents for the sake of his therapy.

Achieving Autonomy in the Family Context

Given a contractual concern for all family members, the therapist challenged some of the intrinsic unfairness in the family members' ways of treating each other. For example, the parents were charged with the task of learning how to acknowledge Bob's actual commitment and investment in their well-being. They were also asked to rethink on their own the implications of their endless list of demands. Was it actually Bob of whom they had a right to expect so much, or was it unfinished business with their families of origin that had subtly shifted their own filial legacies onto their son (see "the revolving slate," reference 1, pp. 65–67).

Over time Bob has been helped to realign the degree to which he was entitled to live his own life with the degree to which he was required to meet some of his parents' expectations of him. Diminishing the pseudo-adversity between Bob and his parents has established a new sense of security in the family. Fresh confidence about the continuing existence of mutual concern and loyalty among family members has freed Bob to mature in a number of ways. By assuring his parents of his fundamental concern for them, he became likely to win more freedom to commit himself to peer relationships. He was also likely to find more room in which to develop his sexual role and even to explore his biological origins. Eventually he will be helped to achieve this goal through learning how to repay his filial indebtedness in age-appropriate terms. In turn, his parents will be helped to define for themselves specifically what they require of Bob. They will be helped to learn how to state their expectations directly rather than by innuendo and to accept and acknowledge Bob's payments of his loyalty obligations in reasonable "installments." Moreover, they will be helped to learn that he cannot be used indefinitely to compensate his parents for what they may have lost in their own childhoods.

If possible, Bob's parents will be helped to revise their expectations of their son by reconsidering how they themselves have or have not met the terms of their own filial legacies. In clinical descriptions it is customary to ascribe inflexible parental clinging almost exclusively in terms of possessiveness and control through power measures. Conversely, we propose that parents who are overburdened with unmet legacy requirements, whether self-imposed or imposed by their own parents, will inevitably overburden their children. Thus recognizing and reworking long-standing unfairness in their own family legacies will not only free parents from a fruitless expenditure of energy in defensive and retributive behavior but will free their offspring from a similar fate. For example, if his parents were to find sources of trust and appreciation within their original relationships, Bob would become more able to "leave" them and invest his energy in his own welfare and development. Becoming less central to his parents' well-being, because of the investments of other people in their lives, he would feel less helpless. Undefined and boundless obligations invariably lead to destructive parentification of children (1).

In future sessions Bob will continue to be a recipient of therapeutic consideration, but the multidirected contextual approach will incorporate his parents as full partners in the therapeutic effort. As therapy progresses the substitutive function of Bob's symptoms is likely to decrease, and signs of his parents' difficulties are likely to surface with increasing clarity. The parents' childhood struggles will emerge, along with long-standing conflicts over their own invisible filial loyalties. Their marital problems will also come to the fore. From Bob's side, age-appropriate, peer-related problems will be raised and considered. Suicide will be viewed as an attempt to claim entitlement in the context of his family's unfulfillable, excessive expectations. Children who are locked into the endless spiral of expectation of perfection on the one hand and their parents' withholding of recognition on the other are candidates for self-destructive patterns. We view the threat of suicide as an eminent example of the pathogenicity of mistrust and the value of the preventive use of a family's trust resources, as opposed to pathology within individuals, which is the preoccupation of traditional, individual-oriented therapy.

By extending his efforts beyond the intrapsychic dynamics of one individual, the therapist avoided the trap of psychological reductionism. Instead, he identified the family's resources for helping Bob rather than choosing either to ignore or foreclose them. He drew family members toward responsible individuation instead of simply reinforcing the isolation, emotional distance, and mistrust that already existed among them. He began the multilateral process of identifying and mobilizing the residual trust that resided in the family, even in the midst of long-standing, acrimonious relating.

ELEMENTS OF CONTEXTUAL THERAPY

Contextual Assessment

In a contextual evaluation indications of injured trustworthiness between parents and offspring are regarded as signals for potential trust-building. Fundamental to the evaluation is the therapist's capacity to assess some acknowledgeable merit in every family member. Merit in relationships emerges from prior investments of trustworthiness that are capable of yielding interest and returns in trustworthy relating. Of course, all relational accounts are composed of both assets and debits. Assets are the sum total of past and present investments of care, concern, consideration, and devotion. Debits are the sum total of inconsideration, lack of acknowledgment, neglect, abuse, emotional or physical abandonment, or any combination of acts amounting to a failure of commitment and resulting in accrued mistrust. In any case, acknowledgment of merit is a first step on the way to fair return. In fact, even the process of taking an inventory of assets and debits can serve to readdress ethically stagnant relating. The weight of therapy is thereby redistributed from an emphasis on the removal, interruption, relabelling, or restructuring of pathological behavior to a concentration on resources inherent in the "merit ledgers" or balances of accounts among people involved in a relationship. (1)

Therapy

Conducting therapy requires specific training in the contextual approach and skill with a broad spectrum of psychotherapeutic methods. The more comprehensive the therapist's competence, the more he or she is able to assess the facets of a client's context and to integrate the four dimensions of contextual therapy into therapeutic planning. Factual circumstances, communication and transactions, psychology, and merit are elements that combine to determine the outcomes of therapy. In Bob's case, some of his family's factual circumstances include his parents' medical reasons for not having a natural child, the age at which Bob was adopted, and information about his natural parents. The fact of adoption also has a built-in legacy requirement of its own. Despite implicit suggestions of irresponsibility customarily ascribed to people who give their children up for adoption, no adoptive child, or anyone else for that matter, can accept the notion that his natural parent is worthless. Consequently, understanding the reasons why their natural parents gave them up is always a task for adopted children.

In addition to factual circumstances, systemic patterns and role structures associated with a family's communication and transactions are of obvious importance to the therapeutic process. These patterns, sequences, and structures represent the overt, symptomatic level of relational exchanges and are richly characterized in the literature of classical family therapy.

A knowledge of psychology is the third dimension of the contextual approach, which presumes familiarity with intrapsychic development and dynamics. The ego strengths and defenses of each family member, for example, provide the therapist with practical knowledge. In the case illustration Bob's mother may be diagnosed as having a rigidly paranoid type of personality. Her consistent projective inclinations suggest limitations that are to be considered in designing therapeutic strategies. However, initially it is the adolescent's suicidal inclination rather than his mother's psychodynamic configurations that should be the crucial therapeutic and preventive concern. The individually focused question of bypassing the mother's intrapsychic priorities rather than working them through must be subordinated temporarily to the prospect of danger to Bob's life. Once the immediate reality of this priority has been addressed satisfactorily, his mother's entitlement to make claims in her relationships will also be considered. In any case, from a contextual perspective multilateral considerations of entitlement and valid in-

debtedness should not be guidelines and strategies geared simply to each person's intrapsychic dynamics.

The ethical or trust-building dimension of contextual therapy is its guiding consideration. Given his concern for fairness among relating partners, the contextual therapist presumes that the ethic of filial accountability originates from relational reality rather than from guilt anchored in Bob's superego. Therefore he will be guided by each family member's obligation to recognize the impact of legacy expectations and to acknowledge the merit of each person's contributions to the quality of his or her relationships. This guideline is predicated on the fact that the improved quality of family relationships is a shared interest of all family members.

The multilateral contract marks a transition from diagnosing immediately noticeable intrapsychic symptomatology toward gradually uncovering the facets of relational circumstances. By eliciting trust from all family members the therapist can help each of them turn to him in an atmosphere of growing receptivity to help. Furthermore, the trust elicited by the therapist serves to reveal how Bob's inclinations toward suicide intersect with his mother's relationship with her family of origin.

Trust Building and Therapeutic Conviction

Trust building is both the ideological foundation and the primary tool of contextual therapy. It is the process through which residual trust resources among family members or otherwise significant relationships are identified, elicited, mobilized, and used. It is built on the characteristics that provide balance in life: 1) respect for equitability on every member's own terms, 2) integrated give and take in relationships, 3) mutual consideration and "use" of one another, and 4) redistribution of returns from the joint accounts of trust investments.

Clearly there are other powerful forces at play in determining the visible behavior of relating partners. People are also motivated by needs for affection, dependence, and sexuality. People are inclined to use each other unilaterally as objects for transference, displacement, and substitutive retribution. Contextual therapists integrate these factors and others like them but nevertheless proceed from the central conviction that evolving interindividual trustworthiness is the basic fiber of durable relationships and the shortest route to eradicating skewed and distorted behavior.

Knowledge, skill, and personal conviction are all elements in a therapist's capacity to channel and use trust. As a qualified helping professional, the therapist presents himself as worthy of his clients' trust. Over time he will become privy to private aspects of his clients' lives and help them investigate the loyalties in their families of origin, their marriages, and their capacity to parent. As various family members turn to him for help he himself becomes a major if interim recipient of their trust investments, in part because they sense his conviction about multilateral equitability. Trust between therapist and client can flow in a variety of ways:

1. From the outset the therapist receives trust through the client's act of contracting for help. This initial and usually tentative line of trust may be strengthened through the client's response to the therapist's elicitory measures aimed at encouraging people to take initiative on their own behalf.

2. Once clients have returned trust offered to them by a therapeutic investment in their situation the therapist has his own choice to make in terms of how he will use their trust. The therapist can accept the clients' trust, channel it into his own personal relationships, grow and mature from it, and use it to secure his commitment to a responsible performance of his difficult work, or he can convert his clients' trust into a reservoir that supplies his narcissistic desires of superiority and offers him a power-based notion of therapy. He may even use it as unilateral leverage for refueling his own personal relationships.

3. In the tradition of individually oriented therapy, trust can be channelled into a one-to-one relationship between therapist and client. This mode of using trust can create escalating demands in managing an intensification of transference and countertransference attitudes and needs.

4. Rechannelling trust into the process of strengthening relationships between family members is an alternative to the exclusivity of trust development between client and therapist. Using this option the therapist can inject his own regard for accountability and integrity in relationships. He can help family members reveal one another's unacknowledged consideration and contributions. Through his multidirected trust-building efforts, the therapist can elicit responsible attitudes that may lead to a more genuine dialogue (5) among family members.

Using multidirected trust building as a therapeutic methodology requires a knowledge of legacy expectations, a degree of personal maturity, and a set of convictions that can be brought into dialectic exchange.

The skilled contextual therapist operates with a set of convictions that emerge from both his personal and professional experience:

1. Trustworthiness is a decisive relational factor that cannot be reduced to the individual psychologies of the family members.

2. Trustworthiness follows the regulatory forces of earned merit rather than of power. For example, when a person is "successful" in unilaterally exploiting his partner's trust, he inevitably loses ground in maintaining trustworthiness (balance of accounts).

3. Multilateral investments of trust and consideration among family members enhance each person's entitlement to more satisfactory living (multi-

laterality). At least in part this conviction must emerge through the initiative, personal, and familial experience of the therapist.

4. The therapist's task is to elicit multilateral investments in relationships and to identify healing resources for all relating parties (multidirected partiality). This task is to be differentiated from any tendencies on the part of a therapist to impose his own value judgments.

5. A person's inherited legacy expectations cannot be ignored without an increase in the emotional costliness of living (legacies as present here-and-now relational contexts).

6. Children should not be forced to guarantee age-inappropriate nurturance to their parents or be used as unilateral, captive investors in their parents' depleted accounts of trustworthiness. This conviction is based on the further understanding that both parents and children benefit from balanced parent-child accounts (equitability of interests between parents and children).

The capacity to apply contextual concepts and convictions lies in a variety of skills:

1. Using multidirectionality to elicit and catalyze the active participation of all family members in discovering and mobilizing pockets of residual trust resources (1, chapter 5).

2. Helping people develop appropriate terms for repaying realistic legacy expectations within their specific contexts.

3. Helping unreceptive parents accept their children's attempts to repay them in "installments."

4. Eliciting multilateral investments from participating members of long-term significant relationships without the therapist becoming depleted through the effort. That is, the contextual therapist cannot function indefinitely as a primary source of trustworthiness for his clients or he becomes a captive to expectations that he supply hope, trust, dependent support, limitless empathy, and one-sided partiality to family members.

Many signs indicate that our era has reached a dangerous extreme of relational disintegration. Belief in linear progress toward individuation has resulted in a cost to relational responsibility. It has led to a frightening fragmentation of even nuclear families and to widespread grossly inadequate, often dehumanized child-rearing patterns. Moreover, the disintegration of both small and large communities raises the frightening possibility of a generalized downward spiral of trustworthiness, a condition that leads to pathogenic social patterns.

SUMMARY

The contextual approach stresses relational factors as resources for individual health and strength. Its focus on interindividual trust in family life and legacies introduces a fundamentally new perspective to therapy: the simultaneous consideration of more than one human being as the valid subject of therapeutic intervention. The approach retains an interest in both the singularity of individuals and the transactional-communicational systemic discoveries of classical family therapy.

Therapeutic focus on actively facing and planning for balanced relational accounts leads to a resource-based orientation to therapy. Contextual therapy takes care not to negate signals that indicate pathology but interprets them as evolving from a condition of stagnation between two or more people. Stagnation is usually the result of a lack of trustworthiness in relationships.

Work with families evokes the importance of trust and trustworthiness more sharply than individual-oriented therapy. Close and continuous observation of many families leads the therapist to rediscover the significance of trust over and beyond its worth for early childhood development. If basic trust is essential to emotional development in early childhood, merited trust is a fundamental need of adults. Born of multilateral investments of care and consideration among family members, merited trust is the primary principle of contextual therapy, and trust building is its primary strategy. Initially, merited trust is governed mainly by basic legacies. Parental accountability and filial responsibility are basic legacies that leave an impact, whether or not the participants' behavior seems to justify an investment in each other's welfare. Real or prospective legacy sharing is a residual trust resource that can compensate for transitory unfairness.

Contextual therapy is a complex scheme of interlocking concepts and methodological strategies. Its implications and skillful application require extensive study, training, and experience. While trust building is its guiding principle and its primary goal, at base the contextual approach is eclectic and noncompetitive. It underlies and incorporates all viable therapeutic orientations and strategies. The contractual implications of multidirected consideration of all persons affected by the intervention is a guiding principle for psychotherapy as a whole, and in our view this contract is bound to affect all forms of future professional practice, including individual therapy or counseling. In addition, contextual therapy's approach to relationships may have far-reaching implications for a fresh and creative reconsideration of disintegrative social patterns.

Finally, it should be noted that the multilateral perspective of contextual therapy should lead to an ethic of relationships that requires family members to define or redefine the balance of their relationships. In no way should this process be confused with judging or moralizing. Instead, it is a caring responsibility for the future, i.e., prevention in a genuine sense. The study of early development provides evidence for the relevance of present family behavior to the life options of the dependent offspring. At a more advanced state of

evaluation, the value of any psychotherapy will have to be assessed in terms of both curative and preventive impacts. Its multidirected accountability does not only render contextual therapy ethically sound and legally secure, it also provides it with a built-in preventive relevance.

Notice to Clinical Investigators

Under program support from the Foundations' Fund for Research in Psychiatry, three research laboratories have been designated as resource groups for clinical investigators doing blood level research with antianxiety, antidepressant, and antipsychotic drugs. Investigators who seek to establish the reliability of their methods or those who wish to participate in a proficiency testing protocol should contact the appropriate group listed below.

Benzodiazepine anxiolytics: Drs. Greenblatt/Shader, telephone (617) 956-6997

Tricyclic antidepressants: Dr. Perel, (412) 624-2198

Phenothiazine antipsychotics: Dr. Davis, (312) 996-1065

Am J Psychiatry 137:7, July 1980

Overview: Public Health Issues in Tardive Dyskinesia

BY GEORGE GARDOS, M.D., AND JONATHAN O. COLE, M.D.

Public health concern over tardive dyskinesia has been rising, but the magnitude of the problem has been undetermined. The incidence of tardive dyskinesia is unknown, and prevalence rates yield conflicting and possibly misleading estimates. The natural course of tardive dyskinesia is highly variable: in some patients (probably many fewer than previously believed) it is irreversible. No currently available therapeutic agent satisfies the criteria of safety, marked effectiveness, and prolonged efficacy in the treatment of tardive dyskinesia. Primary prevention involves reducing antipsychotic drug exposure, secondary prevention involves early diagnosis and prompt intervention, and tertiary prevention involves clinical measures to reduce disability and to treat severe cases vigorously. Educational methods that disseminate knowledge and influence prescribing habits need to be identified and used more widely.

Tardive dyskinesia, an involuntary movement disorder characterized by choreoathetoid movements, tics, grimaces, and dystonia, has aroused great concern in psychiatry. One source of this concern is the possibly iatrogenic nature of the disorder and the likelihood of increasing litigation. Perhaps the major reason for worry is that no suitable alternatives to antipsychotic drug treatment are on the horizon; consequently, tardive dyskinesia is not likely to diminish and may in fact become more widespread. A quarter of a century into the neuroleptic era, drug-induced tardive dyskinesia has emerged as a significant public health problem. The response of the profession has shifted from curiosity and mild concern to panic, but there is no clear agreement on the magnitude of the problem. In this article we will approach key issues relating to tardive dyskinesia from a public health viewpoint. We will present relevant data from the literature as well as from our own research. We will offer promising avenues toward resolving problems wherever possible.

INCIDENCE OF TARDIVE DYSKINESIA

Incidence (as distinct from prevalence) refers to the number of new cases emerging in a well-defined population during a given time period. The true incidence of tardive dyskinesia is unknown. Prevalence rates (usually expressed as the proportion of patients with tardive dyskinesia at a particular time in a treatment facility) are often confused with incidence. The reported prevalence of tardive dyskinesia ranges from .5% to 40% in chronic drug-treated patients (1). Baldessarini (2) obtained a mean prevalence of 15% from 25 publications up to 1972 covering 28,000 patients. More recent reports, however, have placed the prevalence of tardive dyskinesia close to 50% in both in- and outpatient populations (3–5).

It is premature to draw alarming conclusions from such high and seemingly increasing prevalence rates. The methodological problems inherent in survey research are formidable and include the following: 1) arbitrary definitions of tardive dyskinesia, 2) measurement problems, particularly questionable reliability of rating scales (6), 3) generalizability (study populations often consist of elderly hospitalized patients, and the findings do not apply to drug-treated schizophrenic patients in the community), and 4) the confounding effect of concurrent antipsychotic treatment, which may influence the level of observed dyskinesia.

In view of the problems with survey research, it is most unfortunate that systematic data on the incidence of new cases of tardive dyskinesia are unavailable. Preliminary findings, however, have been obtained recently by one of us (J. O. C.), who found 15–20 inpatients with dyskinetic movements of recent (3–6 months) origin during consultation work at McLean Hospital over a 12-month period. Approximately 400 schizophrenic patients are admitted or readmitted to McLean each year; thus the incidence figure is roughly 4%–5%. The risk for a schizophrenic inpatient at McLean Hospital to develop tardive dyskinesia in 1 year is 4%–5%. Assuming that the risk remains the same during a second, third, and subsequent years, the risk for such a patient of developing tardive dyskinesia

Presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12–18, 1979. Received March 16, 1979; accepted Aug. 7, 1979.

might be 20%–25% over a 5-year period. It should be noted that many of the patients at McLean had prolonged histories of drug therapy and multiple hospitalizations, although some developed dyskinesia after only a few months of drug exposure.

The major public health concern is the real possibility that with each passing year of widespread antipsychotic use, increasing numbers of patients will develop tardive dyskinesia. Gathering reliable incidence figures from a wide range of populations at risk over a long time period appears to be the only direct method of clarifying this issue.

NATURAL HISTORY OF TARDIVE DYSKINESIA

Natural history refers to the long-term course of tardive dyskinesia in patients in whom no specific interventions are carried out to influence the movement disorder. The public health issue is whether tardive dyskinesia is progressive and, if so, whether severe and disabling forms of the disorder develop with any great frequency.

Few studies have followed patients for more than a few weeks. A study by Heinrich and associates (7) showed that 40% of a sample of patients underwent spontaneous remission of tardive dyskinesia at 15-month follow-up on continued fixed-dose antipsychotic treatment. Degkwitz and associates (4) re-examined a cohort of 70 chronic drug-treated patients after 2 years. In 26% of the patients tardive dyskinesia increased in severity, in 23% there was no change, and in 10% the movements lessened. Fifteen percent of the patients revealed tardive dyskinesia for the first time at the second evaluation. Chien and Cole (8) reported no statistically significant changes in the dyskinetic movements of 24 patients with tardive dyskinesia after 18 months. In two studies Crane (1, 9) reported considerable increases in the number of patients with tardive dyskinesia at 1-year and 4½-year follow-up, respectively. The demonstration of marked spontaneous fluctuations of tardive dyskinesia ratings in longitudinal studies (10) may partially explain the different findings between studies.

At this time we can reasonably conclude that the meager research evidence available does not point to a progressive disorder in the majority of affected patients.

SEVERE TARDIVE DYSKINESIA

Although most patients show mild degrees of dyskinesia, quite severe cases of tardive dyskinesia have been clearly documented. Moreover, many patients, particularly younger individuals, are distressed by even mild dyskinesia and may become socially withdrawn as a result.

Marked dystonias tend to be seen in patients under 50 years of age and may lead to a disturbing degree of grimacing, contortions of the body, instability of posture, and gait disturbances (11), occasionally resulting in falls and injuries (12). Marked oral dyskinesia may result in dental problems: ill-fitting dentures, bruxism, broken teeth, tongue biting, and oral ulceration (13–15). Chewing and swallowing may also become impaired (14, 16).

In 1979 Ayd (17) described the following respiratory abnormalities induced by severe tardive dyskinesia: grunting, puffing, snorting, and disturbances of rate, rhythm, and depth of respiration. Dyspnea and chest pain (18), as well as life-threatening respiratory and gastrointestinal complications, have been reported in single cases (19). Speech impediments induced by tardive dyskinesia have also been noted (12). Marked weight loss has been described in patients with severe generalized dyskinesia (12, 20, 21). Despondency over the apparently irreversible movement disorder may induce suicidal potential (20). A 1978 report (22) suggested that life expectancy may be reduced in patients afflicted with tardive dyskinesia in comparison with matched controls.

The above description of serious complications is based on case reports. No reliable incidence figures are available for severe and disabling tardive dyskinesia; fortunately, however, the incidence appears to be extremely low. In our 12-year follow-up study of extensively drug-treated chronic hospitalized schizophrenic patients (the report is in preparation), not a single case of disabling tardive dyskinesia emerged in 89 patients. According to data we collected in an informal survey of 20 experienced investigators of the disorder, we estimated that the prevalence of functional impairment persisting after drug withdrawal was less than 10% of patients with dyskinesia.

Overall, we may state that although tardive dyskinesia can become an extremely serious and disabling condition, the more severe forms are rare and are not likely to reach epidemic proportions in the foreseeable future. The public health importance of severe tardive dyskinesia has to be evaluated in the context of the benefits that antipsychotic drug treatment provides for a tremendous number of psychotic patients.

IRREVERSIBILITY OF TARDIVE DYSKINESIA

Prognosis is a key public health issue. If tardive dyskinesia is reversible in most cases, then the major goal might be seen as the optimal management of the disorder, i.e., reversing the condition with the least risk of psychotic relapse. On the other hand, if a substantial number of cases of tardive dyskinesia proved to be irreversible, the paramount public health task would be prevention.

We discussed the natural history and likely outcome

TABLE 1
Summary of Studies of Effects of Antipsychotic Drug Withdrawal on Tardive Dyskinesia

Study	Number of Patients[a]	Age Range (years)	Population Studied	Duration of Observation (months)	Effect of Withdrawal on Tardive Dyskinesia
Uhrbrand and Faurbye (24)	17	52–80	Chronic psychotic inpatients	7–23	Persisted in 10 patients (59%)
Hunter and associates (25)	13	56–84	Chronic female inpatients with dementia	8–36	Unchanged in all patients
Paulson (26)	33	30–80	Inpatients in a state hospital	3	"Most movements failed to subside"
Degwitz (27)	10	20–80	Chronic schizophrenic inpatients	9	Persisted or intensified in all patients
Edwards (28)	20	45–84	Chronic female inpatients	10–12	Persisted in 18 patients; 5 patients became worse
Crane (29)	37	35–57	Chronic schizophrenic inpatients	6–24	Persisted in 36 patients; 10 patients became worse
Hershon and associates (30)[b]	23		Chronic schizophrenic inpatients	4	Oral dyskinesia unchanged
Yagi and associates (31)	19	23–72	Chronic psychotic inpatients	24	Disappeared in 10 patients; persisted in 6 patients; 3 patients regressed
Quitkin and associates (32)	11	24–55	Patients in an aftercare clinic	2–12	Disappeared in 10 patients; persisted in 1 patient
Jeste and associates (33)[c]	21		Schizophrenic and manic-depressive inpatients		Disappeared in 12 patients; persisted in 9 patients

[a]Only patients showing tardive dyskinesia before drug withdrawal were included.
[b]The age range for the patients in this study was not given; the mean age of the patients was 56.5 years.
[c]The age range for the patients in this study was not given; the mean age of the patients was 62 years. The number of months the study lasted was also not given; the mean length of the period of observation was 13 months.

when no specific treatment for tardive dyskinesia is given in the section above. The clinically obvious and most common intervention for tardive dyskinesia is to attempt to reverse the condition by discontinuing the drug or reducing its dose. Withdrawal of antipsychotic drugs and occasionally of antidepressants may result in an increase in the severity of tardive dyskinesia or in the appearance of new dyskinetic movements. The prevalence of withdrawal-emergent dyskinesia has been estimated to be 5%–40% (1). Many of these cases turn out to be withdrawal dyskinesias that are self-limited and usually disappear within 6 weeks (23). If the dyskinesia persists beyond 6 weeks, the likelihood is that the tardive dyskinesia was previously suppressed by drugs ("covert dyskinesia").

The long-term prognosis in patients with tardive dyskinesia who are no longer receiving antipsychotic medication is variable. Case reports and research studies provide examples of all possible results—from complete disappearance of abnormal movement to treatment-refractory, progressively worsening cases.

Table 1 summarizes studies of patients with tardive dyskinesia whose antipsychotic medication was discontinued and who were followed for several months. The data in the table tend to support the view that chronically institutionalized elderly patients with prolonged exposure to antipsychotic drugs are most likely to show irreversible tardive dyskinesia.

The 3 most recent studies (31–33) showed that patients who had received drug treament for a relatively shorter time were more likely to develop reversible dyskinesias. Despite the apparent statistical association between prolonged pharmacotherapy or older age and irreversible tardive dyskinesia, the prediction of prognosis for the individual patient remains problematical. The unpredictability of changes in tardive dyskinesia following drug withdrawal is highlighted by the results of the questionnaire we sent to 20 investigators of tardive dyskinesia. The data we gathered revealed amazing variability of opinions and experiences regarding outcome. The reported frequency of tardive dyskinesia persisting in patients whose drug treatment had been withdrawn for 3, 6, 12, and 24 months ranged from 0% to 100%.

Dose reduction is often preferred to abrupt drug discontinuation because it provides better protection against psychotic relapse. Changes in the status of tardive dyskinesia following dose reduction show the same variability of outcome as they do after drug withdrawal, but the former changes tend to be less dramatic.

From the neuropharmacological perspective, it is tempting to assume that reversible dyskinesias reflect reversible and permanent tardive dyskinesia reflects irreversible neurochemical changes at the synapses of the basal ganglia. Using dopamine agonists, Friedhoff and associates (34) demonstrated receptor sensitivity modification in patients with tardive dyskinesia. This raises the hope that, in some patients hitherto regarded as showing irreversible tardive dyskinesia, the neurochemical changes might be altered and the prognosis may not necessarily be bleak.

The clinical concern and public health focus on the possibly irreversible cases of tardive dyskinesia lose

sight of the fact that prolonged use of antipsychotic drugs may produce a whole range of adverse effects on the CNS. In a scholarly review, Crane (35) described three types of "neuroleptic induced encephalopathies": 1) reversible, 2) irreversible or slowly reversible, and 3) juvenile reversible symptoms. The irreversible category includes hypotonia, dystonias, and Parkinson-like syndromes in addition to the well-recognized manifestations of tardive dyskinesia. To underscore Crane's view, a number of surveys that have focused primarily on tardive dyskinesia have also shown an even higher prevalence of parkinsonian manifestations in chronic drug-treated patients, often despite usual anti-Parkinson drug treatment (3, 36). Not only are there apparently treatment-resistant cases of drug-induced Parkinson-like syndromes in numbers comparable to those of tardive dyskinesia, the functional impairment resulting from akinesia, rigidity, and tremor may well equal if not exceed the usually minimal functional disturbance of tardive dyskinesia. The need for a more comprehensive approach to the problem of the long-term side effects of antipsychotics in place of a narrow focus on tardive dyskinesia alone cannot be overemphasized. The key public health issue remains the risk-benefit ratio when the risk represents the aggregate of all the hazards of antipsychotic drug treatment versus the psychosocial benefits accruing from effective drug treatment.

DRUG TREATMENT OF TARDIVE DYSKINESIA

The following questions need to be answered when assessing the public health impact of a therapeutic agent: 1) What proportion of afflicted patients respond? 2) How effective is the treatment in severe cases? 3) Are the benefits evancescent or long-lasting? and 4) What is the risk-benefit ratio of the proposed treatment?

The major classes of drugs used in the treatment of tardive dyskinesia include dopamine antagonists, cholinergic drugs, and γ-aminobutyric acid (GABA) agonists (37). No drug or therapeutic method has emerged so far that has proved satisfactory in terms of the criteria raised above. Although many clinical drug trials demonstrate improvement in a sizable proportion of patients, few patients in any given trial have shown more than 50% improvement. Long-term clinical trials in tardive dyskinesia are conspicuous by their absence.

Side effects may severely limit the therapeutic potential of otherwise highly promising drugs, such as clozapine or choline. Severe and functionally impaired cases are often effectively treated with large doses of dopamine blockers (e.g., haloperidol). However, in such instances, the possibility of other side effects and the potential "breakthrough" of movements may raise the risk-benefit ratio as a legitimate concern.

From a public health view, the treament of tardive dyskinesia is unsatisfactory. Safe, effective, and specific treatment methods are lacking. Nonspecific measures such as dose reduction may be thought of as belated efforts at prevention with no certainty of success in the individual patient. Therefore, the search for newer and better therapeutic agents needs to be pursued relentlessly, and currently available drugs should be evaluated in long-term studies.

PREVENTION

The public health import of the prevention of tardive dyskinesia hardly needs stressing. Borrowing from community psychiatry, we can conceptualize the problem in terms of primary, secondary, and tertiary prevention.

Primary Prevention

Primary prevention of tardive dyskinesia involves identifying and eliminating etiological factors. The two major variables are antipsychotic drug therapy and age: tardive dyskinesia is virtually unknown in young people who have had no previous exposure to antipsychotic drugs. Because antipsychotic compounds remain the cornerstone of the treatment of acute and chronic schizophrenia, these drugs cannot be replaced. While the search continues for new antipsychotics with little or no extrapyramidal side effects, efforts have also been directed at better delineating the risk factors associated with neuroleptic drug exposure. To date, research focusing on the interrelationship between tardive dyskinesia and drug variables such as dosage, type of drug, anti-Parkinson drugs, treatment interruptions, and duration and amount of drug exposure has yielded conflicting and confusing results (6). Nevertheless, the goal of minimizing exposure to antipsychotic drugs as a primary preventive measure appears to have face validity and may be accomplished as follows:

1. Avoidance of antipsychotics whenever suitable alternatives are available (e.g., lithium or antidepressants for patients with affective illness, antianxiety agents for neurotic anxiety).
2. Optimal use of antipsychotic compounds. Many chronic schizophrenic patients receive antipsychotic doses greatly in excess of what is needed (9, 38, 39). Furthermore, patients who have had one or two psychotic episodes are not necessarily candidates for indefinite drug therapy (40).

Secondary Prevention

Secondary prevention of tardive dyskinesia concerns early case finding and prompt intervention and is based on the following assumptions: 1) tardive dyskinesia has a better prognosis if recognized early and 2)

intervention in early tardive dyskinesia is less harmful in the long run than allowing the disorder to take its natural course.

The above statements appear so obviously true that it becomes tempting to ignore the fact that little solid data exist to substantiate them. Very little research has been conducted on the course of early dyskinesia. It is generally believed that in most patients tardive dyskinesia develops insidiously, early signs being fine vermicular movements or restlessness of the tongue, mild choreiform finger or toe movements, and facial tics or frequent eye blinks. Clinical recognition of early tardive dyskinesia involves systematic observation of patients in a search for the above-mentioned signs. Crane (41) recommended examination of drug-maintained patients every 3 months for signs of tardive dyskinesia. A more aggressive method of detecting the disorder may involve drug holidays for a few days or weeks. A drug-free period of less than 3–4 weeks is usually too short to precipitate psychotic relapse but long enough to uncover dyskinesia. Other, so far experimental methods of detecting early or clinically undetectable dyskinesias include the administration of dopaminergic or anticholinergic challenge doses (42) and electrophysiological techniques (43, 44).

Therapeutic intervention for early tardive dyskinesia may involve a series of diagnostic and therapeutic measures. First, remediable neurological causes of dyskinesia (e.g., Wilson's disease) should be excluded by appropriate tests and by neurological consultation in doubtful cases. The indications for continued antipsychotic therapy should be reviewed and suitable alternatives selected (e.g., lithium carbonate for patients with affective disorder). In patients who are known to require antipsychotic drugs, attempts should be made to find the minimal effective dose level, although no standard method of titrating antipsychotic dosage has been established (45).

Jus and associates (38) have recently shown that stepwise reduction of antipsychotic dosage together with low doses of haloperidol or reserpine was effective in substantially reducing moderate and severe tardive dyskinesia in chronic schizophrenic patients over a four-year period. In patients who have never received an adequate trial without antipsychotics, drug withdrawal could be considered (46), but this recommendation is not generally accepted because of the substantial risk of psychotic relapse (40). Other suggestions to ameliorate or arrest tardive dyskinesia include drug holidays, drug-free weekends, withdrawal of anti-Parkinson drugs, and switching to an antipsychotic with less extrapyramidal effects; however, the research evidence in support of these recommendations remains unconvincing.

In summary, the effectiveness of intervention in arresting or reversing the course of early dyskinesia appears to be promising but remains to be established in longitudinal studies.

Tertiary Prevention

The public health goal in tertiary prevention is to limit and, as far as possible, ameliorate the disability resulting from already established tardive dyskinesia. The procedure is more or less synonymous with the clinical management of the disorder. The specific steps are identical with the intervention in early dyskinesia. In severe cases, the addition of specific drugs to reduce dyskinetic movements may become imperative.

Education

A further important issue in the area of prevention is the efficiency of educational methods such as the continuing medical education (CME) program. Specifically, it is not known how readily expert opinion and established research findings influence the prescribing behavior of the practicing psychiatrist. A disquieting fact emerged from a report by Crane (9) suggesting that presentation of relevant facts in lecture form may lead to no measurable changes in drug prescribing habits, a finding in accord with the experience of most teachers of psychopharmacology. Perhaps other educational methods, such as journal articles, symposia, courses, and audiovisual materials, may be superior techniques for disseminating information and inducing desirable changes in treatment practices. Nevertheless, as the recent history of the slow and spotty implementation of birth control methods in overpopulated areas of the world clearly indicates, there is a long and arduous process from knowledge of preventive techniques to improved public health.

CONCLUSIONS

More effective prevention of tardive dyskinesia is dependent on progress in the isolation of etiological factors and on the arrival of more effective therapeutic agents. Meanwhile, promising avenues include reducing neuroleptic drug exposure, early diagnosis of tardive dyskinesia, and rational clinical management of established cases.

Carbamazepine in Manic-Depressive Illness: A New Treatment

BY JAMES C. BALLENGER, M.D., AND ROBERT M. POST, M.D.

The authors evaluated carbamazepine (Tegretol), a drug of choice for treatment of temporal lobe epilepsy, in a double-blind placebo-controlled trial in patients with manic-depressive illness. Seven of 9 manic patients had a partial to marked response; several also showed relapses when placebo was substituted and improvement when carbamazepine was reinstituted. Five of 13 depressed patients showed significant improvement in depression ratings; 3 additional patients experienced partial relapse when placebo was substituted. Carbamazepine might also have prophylactic as well as acute efficacy in patients with both phases of manic-depressive illness, including some patients who do not respond to lithium. Therapeutic effects were achieved with 600–1600 mg/day at blood levels of 8–12 μg/ml with relatively few side effects. Carbamazepine may prove to be a useful additional treatment for affective illness.

Carbamazepine (Tegretol), an iminodibenzyl derivative, has many current therapeutic uses, including the treatment of trigeminal neuralgia (1), pain syndromes (2, 3), diabetes insipidus (4, 5), and dystonic disorders (6), and is one of the treatments of choice for temporal lobe epilepsy (7). We initially became interested in carbamazepine as a potential new agent in the treatment of manic-depressive illness because of our theoretical interest in its temporal/limbic anticonvulsant activity in patients with temporal lobe epilepsy, particularly in the light of its major psychotropic effects in these epileptic patients.

It has been found in 40 reports that approximately 50% of 2,500 patients with epilepsy improved psychiatrically when given carbamazepine (8). Most of these reports were of uncontrolled clinical trials; however, 7 double-blind placebo-controlled trials (9–15) also generally supported the finding that carbamazepine has a significant psychotropic effect. Other studies (1, 8, 10, 16–30) have demonstrated that the interictal personality difficulties associated with chronic epilepsy improve in both children and adults given carbamazepine. Patients describe feeling brighter and more alert and show improvement in initiative and social behavior as well as in the affective symptoms of anxiety, irritability, and depression. In addition, the phasic disorders of epilepsy that resemble functional psychiatric syndromes, particularly manic-depressive illness and schizophreniform psychoses (31–35), often improve in a dramatic and lasting manner with carbamazepine. A large percentage (33%–90%) of these syndromes improve, at times without concomitant reduction in the frequency of seizures (8). In addition, studies have demonstrated that patients who have nonspecific EEG abnormalities without overt epilepsy but who have behavioral problems, often including gross psychopathology and violent behavior, improve on carbamazepine (26, 27, 36–40).

We have postulated a "kindling" model of affective illness in which cumulative bioelectrical changes, particularly in the limbic area, secondary to repeated biochemical or psychological stresses, could result in abnormal limbic neuronal sensitization and major psychiatric disturbances (41–46). Carbamazepine's unique neurophysiological properties as a limbic anticonvulsant and antikindling agent (see the Discussion section) lead us to feel that the drug might be able to usefully modify this type of postulated disorder. Because of these converging theoretical, clinical, and neurophysiological considerations, we began a double-blind, placebo-controlled trial with carbamazepine in manic-depressive illness (44, 45). To our knowledge, these studies in affective illness represent the first clinical trials outside of Japan and the first double-blind placebo-controlled report of carbamazepine's efficacy.

Open clinical trials with carbamazepine in affective illness in Japan (47, 48) suggested that carbamazepine might be effective in manic-depressive illness. Okuma and associates (48) reported that carbamazepine was effective in about 50% of 64 acutely manic patients and in 3 of 9 depressed patients. There was a higher incidence of prophylactic effects in recurrent mania (71%) and depression (64%) in a sample of 31 patients. These positive effects were observed in some patients who did not respond to lithium. In these studies (48) carbamazepine was added to existing drug treatments, often including neuroleptics, lithium, or antidepressants,

Revised version of a paper presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12–18, 1979. Received Aug. 21, 1979; revised Feb. 1, 1980; accepted Feb. 22, 1980.

and double-blind placebo controls were not used. However, Okuma and Kishimoto (49) compared carbamazepine and chlorpromazine in acute mania in a double-blind trial. Placebo controls were not used, but both drugs were effective in acute mania; no significant differences were found between the drugs, although there were fewer in the carbamazepine-treated patients.

We are reporting our 3-year experience with the first 24 manic-depressive patients to complete the clinical trial. We have observed that carbamazepine has antimanic as well as antidepressant and prophylactic effects in affective illness. We have published preliminary results for the first 10 patients studied in a case report format (44, 45).

METHOD

Patients were hospitalized in a metabolic research ward at the National Institute of Mental Health in Bethesda, Md. They were diagnosed after an extended period of observation according to the Research Diagnostic Criteria (RDC) of Spitzer and associates (50). Twenty-two patients were diagnosed as having primary affective disorder and 2 as having schizoaffective psychosis. Oral and written informed consent was obtained for the clinical trial and all procedures. Patients with hematologic, cardiac, hepatic, or renal disease were excluded.

It should be emphasized that medical histories, neurological examinations, and routine EEGs were negative for any evidence of seizure disorder or other neurological difficulties. Brain computerized axial tomography (CT scans) and clinical lumbar punctures were also within normal limits for all patients. One patient received many EEGs, including sleep recordings and an EEG with nasopharyngeal leads during an episode of activated psychosis; all of these were within normal limits.

Trials with carbamazepine were accomplished in a double-blind fashion and were preceded by a 2-week placebo period and followed by a placebo period of several days to weeks. When relapse occurred following placebo substitution, carbamazepine was reintroduced for a second time whenever clinically possible. Carbamazepine was generally started at 200 mg given twice daily with meals and increased, as tolerated, in 200-mg increments to a maximum dose ranging between 600 and 1600 mg/day. Serum samples were obtained before the morning dose and were analyzed approximately twice weekly for carbamazepine levels; we attempted to maintain serum levels between 8.0 and 12.0 μg/ml. Blood samples were obtained twice a week for white blood cell count, hemoglobin, platelet count, liver function tests, and blood urea nitrogen for the first 6 weeks and then weekly thereafter.

Clinical response to carbamazepine was primarily assessed using global ratings of depression, mania, psychosis, anxiety, and anger rated twice daily using a 15-point Bunney-Hamburg modified rating scale (51). The ratings were done by consensus of experienced nurse raters who were blind to the drug trial. Self-ratings of mood and side effects were also obtained twice daily, and Brief Psychiatric Rating Scales (BPRS) were rated by nurses three times a week. Clinical response in mania was defined as follows: marked improvement represented a decrease in nurse ratings of 4 or greater or the absence of mania, moderate improvement represented decrease of 2–4 points, partial improvement represented a decrease of between 1 and 2 points, and a poor response represented a reduction of less than 1 point (see table 1). Response in depression (see table 2) was defined as good if the nurses' ratings fell more than 2 points, moderate if the ratings declined more than 1.5, partial if the reduction was between 1.0 and 1.5, and poor if the reduction was less than 1 point. This range of antidepressant improvements is the range we have observed on our unit with tricyclic antidepressants.

Six of the 9 manic patients developed their manic episodes after several weeks of hospitalization; these were often so severe that clinical management required rapid treatment and carbamazepine administration was started. Although each of the 9 manic patients had been in the hospital and receiving placebo for at least 2 weeks and in the hospital for a mean of 60±20 days before the trial, treatment with carbamazepine was started after 2–3 days of moderate to severe mania in some cases. The baseline ratings were taken from the 2 days (or 3 when the data were available) preceding the trial. The baseline ratings in the depressed patients were based on the week before the trial. Selected patients who responded favorably, particularly if they had previously been unresponsive to lithium, were given carbamazepine as a prophylactic agent following discharge.

RESULTS

Antimanic Responses

Table 1 summarizes the results for the 9 manic patients. Four patients had marked overall clinical responses, 1 patient had a moderate response, and 2 others had partial responses. Four of the patients had major clinical relapses when placebo was substituted for carbamazepine. Five of the 7 patients who experienced at least a partial positive response or better had been previously unresponsive to lithium. In table 1, the mean of the twice-daily global ratings made by nurses from the baseline period are compared with ratings from week 4 by group t test for each individual (52). Five trials were statistically significant. When t values from these individual trials were combined according to the method described by Winer (53), there

[a]This patient responded well to blind reinstitution of carbamazepine.
[b]Manic episode on placebo was self-limited.
[c]There is evidence that carbamazepine had a prophylactic effect on this patient's mania during a 1½-year follow-up.
[d]This patient was hypomanic; the t test was not applicable because there was no variance in mania ratings; however, this patient's hypomania completely resolved when he was treated with carbamazepine.
[e]The trial was discontinued when the patient developed a skin rash.
[f]This patient had not received previous lithium treatment.

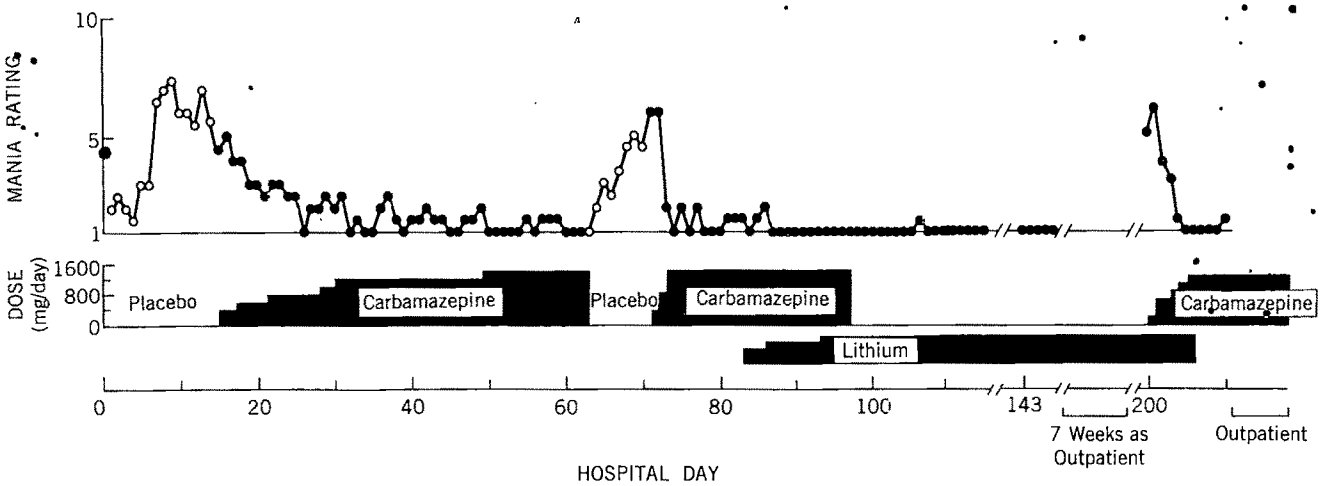
[a]BP=bipolar, UP=unipolar, SA=schizoaffective.
[b]Despite a significant improvement in depression ratings, this patient continued to cycle between depression and hypomania during carbamazepine treatment.
[c]There is evidence that carbamazepine had a prophylactic effect on this patient's depression during follow-up maintenance treatment.
[d]After 3 weeks this patient was treated with carbamazepine and chlorpromazine and demonstrated an unequivocal benefit from carbamazepine. She relapsed twice; on both occasions her dose had been reduced.

was a statistically significant group improvement ($p<.001$). Improvement in mania ratings was also significant by the more conservative paired t test ($p<.05$).

Figure 1 illustrates the marked improvement in the nurses' ratings of mania across three trials in a 39-year-old woman (patient 131) who had been transferred from a nearby state hospital for treatment of a manic episode of 3 weeks' duration. The onset of her illness began with a hypomanic episode at age 19. The patient experienced four depressions over the next 10 years; these often required hospitalization and ECT. In the past 10 years she had been hospitalized 15 times, primarily for manic episodes. Despite continued outpatient treatment with lithium, she had become manic five times in the 2 years before admission to NIMH. On admission she was hyperactive, talking rapidly, confused, hypersexual, and markedly labile in her affect. She alternated between joviality, weeping, and irritability and was mildly paranoid without evidence of hallucinations or delusions.

Two days after carbamazepine treatment was instituted her mania began to improve; she was completely recovered after 14 days (see figure 1). When placebo was substituted for carbamazepine, she became hypomanic the next day and by the fourth day was as severely manic as she had been before the carbamazepine treatment. When carbamazepine was again reinstituted, she improved markedly after 3 days and remained well while receiving carbamazepine. Because of the possibility of poor compliance in taking medication at home it was unclear whether she had previously not responded to lithium. Therefore, she was switched back to lithium, continued to do well, and was discharged on lithium alone. Two months af-

FIGURE 1
Unequivocal Antimanic Response to Carbamazepine in a 39-Year-Old Manic Woman



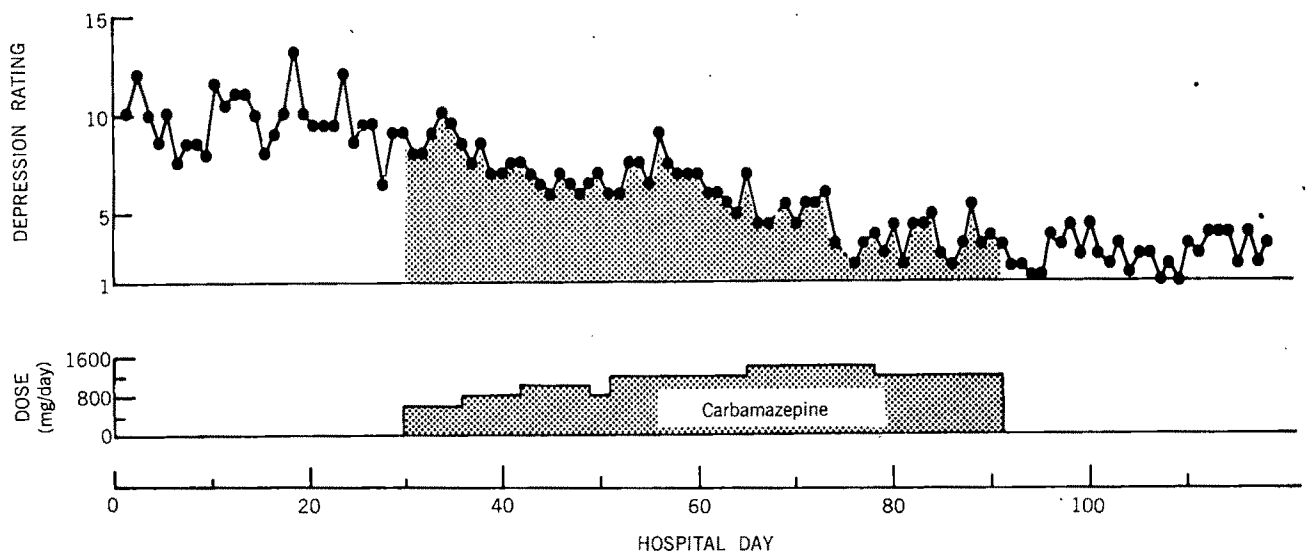


FIGURE 2
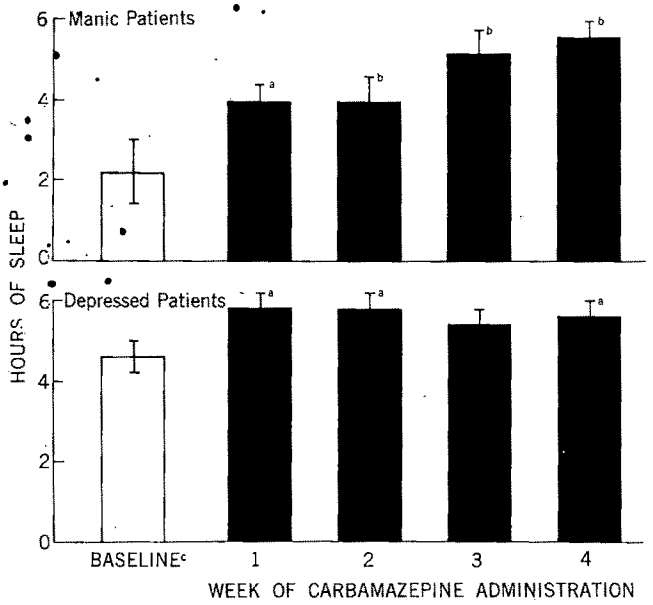
Improvement in Depression in a 63-Year-Old Man with Bipolar Illness Treated with Carbamazepine



ter discharge she became manic while on lithium at therapeutic blood levels and was rehospitalized. She was again treated with carbamazepine, with rapid resolution of her third manic exacerbation (see figure 1), and discharged on carbamazepine.

Antidepressant Responses

Table 2 summarizes the antidepressant responses in the 13 depressed patients treated with carbamazepine to date. Four patients had good overall clinical responses, and 1 had a moderate response. Eight additional patients had partial or poor antidepressant responses to carbamazepine. Although 3 patients with incomplete clinical improvement had limited relapses when placebo was substituted and 3 more had probable relapses, only 1 patient (patient 103) had a definitive and major clinical relapse from a recovered state. Four patients who responded to carbamazepine and 2 who did not had evidence of previous incomplete or poor responses to lithium. Three patients had evidence of carbamazepine prophylaxis against recurrence of depressive episodes. This included 1 patient (patient 103) who has remained well for 22 months as an outpatient except for a brief relapse following a dose reduction.

When the baseline depression ratings from the week before carbamazepine treatment was instituted were compared with those from the last week of carbamazepine administration by group t test for each individual, improvement was statistically significant in 5 of the 13 trials (see table 2). When t values from these individual trials were combined (53), there was a statistically sig-

GURE 3
fect of Carbamazepine on Sleep in 9 Manic Patients and 13 Depressed Patients

[a]The patients' sleep significantly improved ($p<.01$, paired t test).
[b]The patients' sleep significantly improved ($p<.05$, paired t test).
[c]The medication-free period for the manic patients was 2 days; for the depressed patients it was 1 week.

nificant group improvement ($p<.001$). However, in contrast to the trial in mania, there was only a trend for group antidepressant response by two-tailed paired t test ($p<.10$).

Figure 2 illustrates the complete resolution of a depressive episode in a 63-year-old man (patient 112) with a 23-year history of bipolar mood disorder. Initially the patient was severely depressed, with psychomotor retardation, sleep and appetite disturbances, crying spells, anxiety, periods of confusion and unresponsiveness, and feelings of helplessness. The third night after carbamazepine treatment was started his sleep improved, and after 7 days his depression and periods of confusion lessened. By the third week of treatment with carbamazepine (serum level, 7.5 μg/ml), he was concentrating better and his appetite and energy had returned (see figure 2). Because the patient maintained his improvement when placebo was substituted, his marked response was not considered as unequivocally related to the carbamazepine.

Improvement in Sleep

Duration of total sleep was preliminarily monitored by half-hour sleep checks by nurses blind to the clinical trial (see figure 3). There was a statistically significant increase over baseline in the sleep of both the manic and depressed patients that began in the first week and continued through the fourth week. EEG-monitored sleep recordings in 3 of the depressed patients also documented an increase in total sleep during carbazepine administration based primarily on increases in slow-wave sleep.[1]

TABLE 3
Side Effects of Carbamazepine in 24 Affectively Ill Patients

Symptom	Patients with Symptom	
	Number	Percent
Dizziness	7	29
Ataxia	5	21

Tremor	2	8
Nausea	2	8
Poor memory	1	4
Confusion	1	4
Aching in legs	1	4
Weakness in legs	1	4
Blurred vision	1	4
Paresthesiae	1	4
Cardiac arrhythmias	1	4

Side Effects

The side effects encountered were those generally expected with an anticonvulsant medication and were consistent with the side effects observed with the use of carbamazepine in other conditions (54). The most common side effect was dizziness; 30% of the patients complained of this symptom sometime during their trial. A smaller percentage of patients complained of such effects as ataxia, clumsiness, drowsiness, slurred speech, diplopia, and aching or weakness in the legs (see table 3). We were able to manage these side effects in each case by either slowing the increase of the drug or transiently lowering the dose. Sedation was not a common side effect, and no patients developed extrapyramidal side effects.

One patient developed a pruritic rash during carbamazepine treatment that rapidly resolved on discontinuation. In another patient a similar rash cleared after placebo substitution, but because this patient had previously not responded to lithium, carbamazepine was carefully reintroduced; the rash did not reappear. However, this patient did develop moderate suppression of her hematologic indices; carbamazepine was therefore discontinued. An additional patient, a 61-year-old woman, developed atrial fibrillation while taking carbamazepine; this resolved 1 week after discontinuation of the drug. Various degrees of heart block have been observed with carbamazepine (55, 56), and changes in pulse rate, particularly slowing, should be carefully evaluated.

Although major dermatological difficulties (57, 58) and isolated cases of pneumonitis (59) and hepatitis

[1]The improvements in sleep were studied in collaboration with Dr. J. Christian Gillin, Unit on Sleep Studies, Biological Psychiatry Branch, National Institute of Mental Health.

(60) have been associated with the use of carbamazepine, the most serious potential side effect is that of the bone marrow suppression. Ten cases of aplastic anemia felt to be "possibly" secondary to carbamazepine treatment have been reported (61, 62). Although 3 fatal cases were felt to be "probably" related to carbamazepine use, all were observed in middle-aged or older patients treated for tic douloureux. To our knowledge, there have been no cases reported since the late 1960s despite increased carbamazepine use in temporal lobe epilepsy.

In a 1975 review of carbamazepine Parsonage (63) stated, "Its safety has still not been seriously questioned, even after more than ten years of usage, and there seems to be no reason to adopt more than ordinary precautions when administering it." Although most investigators concur that carbamazepine is a safe medication, most recommend that prescribing physicians be alert to signs of fever, sore throat, and petechiae or other hemorrhage and obtain complete blood counts weekly for the first month, every other week for several months, and monthly thereafter to monitor for suppression of hematological indices.

White cell counts, hemoglobin, hematocrit, and platelet count were obtained initially on a weekly basis in our patients. There were no significant changes in hemoglobin, hematocrit, or platelets during the trial. However, there was a significant drop in total white cell count by the second week ($p<.01$), reaching a maximum reduction of 25% at week 2. White cell count rose to baseline and above within 1 week of discontinuation of carbamazepine. The decrease in from approximately 8,000 to 6,000 WBC/mm^3 was still well within the normal range. Significant decreases occurred in both polymorphonuclear leukocytes and lymphocytes; both returned to baseline 2 weeks after discontinuation.

As mentioned above, one patient developed a pruritic rash with carbamazepine that resolved on discontinuation. When carbamazepine was reinstituted, the rash did not recur, but the patient developed decreases not only in white count (from 8200 to 5500 WBC/mm^3), but also in hematocrit (from 42% to 37%) and platelet count (from 322,000/mm^2 to 119,000/mm^2). All hematologic indices returned to normal within 6 days of discontinuation of carbamazepine. The decreases in these indices were not clinically significant, and it is unclear whether or not serious bone marrow suppression would have occurred had carbamazepine been continued.

DISCUSSION

We are reporting the first double-blind, placebo-controlled clinical trial of the anticonvulsant carbamazepine in manic and depressive patients. Although our study is ongoing, the early evidence indicates that carbamazepine has antimanic action in at least a subgroup of manic-depressive patients and that it has a therapeutic spectrum different from lithium carbonate in that some patients who do not respond to lithium respond well to carbamazepine. We also have preliminary evidence that carbamazepine may function as an antidepressant in manic-depressive patients as well as have prophylactic value against recurrences of either type of affective episode.

Four of 9 manic patients had marked clinical responses to carbamazepine; a total of 7 out of 9 had a positive antimanic response to carbamazepine used alone. The drug's antimanic effects were observed within the first week of treatment and continued throughout the 4-week trial. This occurred in the absence of notable daytime sedation and with relatively few side effects. Antidepressant effects had a different time course of onset. Although sleep improved early within the first week of active drug administration, antidepressant effects were not evident until after 2 weeks, as has been reported with many other antidepressant medications.

The on-off design of the trial produced particularly convincing evidence of individual response in several patients. When relapse occurred following placebo substitution, reinstitution of carbamazepine represented an additional clinical trial in that particular patient, although these ratings were not included in table 1. In the 2 patients in which this occurred, carbamazepine was also effective when active drug was administered a second time, and in another patient carbamazepine was markedly effective on three occasions (see figure 1). The character of these responses is also illustrated in our paper in which 10 patients were presented in individual case reports (45). The relapses on placebo substitution did not appear to represent a toxic withdrawal syndrome. Mental status was not clouded, and the manic episode that re-emerged was qualitatively and quantitatively similar to that originally observed before carbamazepine therapy. Moreover, there was no evidence of a withdrawal reaction in the patients who did not respond to carbamazepine, which again suggests that the clinical exacerbation was a reappearance of the original symptoms following carbamazepine discontinuation rather than a toxic drug withdrawal reaction.

Although carbamazepine's antidepressant effects are somewhat less definitively demonstrated at this point, its potential as an antidepressant is no less intriguing. Four of 13 patients had good overall clinical responses; a total of 7 had evidence of positive responses to the drug. The ratings from the last week (see table 2) were chosen to maximize our ability to observe antidepressant effects. However, when ratings from week 4 were compared to the baseline week, the overall significance of the results was not altered. Since there were fewer instances of definitive depressive relapses after placebo substitution, we feel that

the antidepressant effects of carbamazepine remain to be unequivocally demonstrated at this point.

Two depressed and 2 manic patients had evidence of prophylactic benefit from carbamazepine treatment. One patient who had had treatment-resistant rapid cycling for 10 years before carbamazepine treatment and another patient who had had one to four depressions per year for the previous 18 years experienced notable prophylaxis in that they have had almost complete resolution of their recurrent affective episodes for periods of 18 and 22 months, respectively. Another 3 patients showed partial evidence of prophylactic benefit: their affective episodes lessened in severity or incidence. One outpatient, not included in this trial of acute inpatients, was given open carbamazepine for treatment of rapid cycling between severe depression and hypomania that was nonresponsive to lithium; she experienced a complete remission with no affective disturbances for 10 months.

In 2 manic patients who had positive antimanic effects from carbamazepine and in 2 others who failed to respond completely to carbamazepine alone, additional neuroleptic medications subsequently proved to be useful. There is suggestive evidence from Okuma and associates (48) that treatment of manic-depressive illness with carbamazepine may be enhanced by concomitant treatment with neuroleptics or lithium for maximum clinical response.

Patients appeared to respond to carbamazepine doses that achieved blood levels between 7 and 12 μg/ml, similar to the high therapeutic range for epilepsy (64, 65). Despite constant dosage, after 2–3 weeks of treatment serum levels usually decreased, presumably related to the well-described decrease in half-life of carbamazepine secondary to induction of hepatic enzymes (66).

We feel that further clinical trials of carbamazepine are indicated and that carbamazepine may emerge as an additional agent in treating manic-depressive illness, perhaps especially in those patients who are nonresponsive to lithium. If our results are confirmed in further investigations, carbamazepine may find a place in the psychopharmacologic treatment of affective illness either as an adjunctive or alternative treatment. It should be determined whether carbamazepine used in conjunction with other medications, such as neuroleptics or lithium, affords additional benefit beyond the use of the traditional treatments alone. This strategy would then be similar to the combination of several different types of anticonvulsants in the treatment of the epileptic patient. Carbamazepine may also prove to be useful as an alternative and primary treatment in patients who are unresponsive to lithium. It is our preliminary impression that some chronically ill, treatment-resistant, and rapidly cycling patients respond well to carbamazepine. Carbamazepine also has neither the tremor nor renal and thyroid side effects of lithium and, despite widespread use has not been reported to have the acute parkinsonian side effects of the neuroleptics or the more important side effect of tardive dyskinesia.

Carbamazepine, with its antimanic properties, may prove to be free of the problem of induction of mania in bipolar depressed patients that is associated with many other antidepressant medications (67). If this proves to be the case, carbamazepine may assume a unique place in the treatment of depression in bipolar patients in that it would be the only medication in current use, other than lithium, which does not have the potential side effect of inducing mania. If carbamazepine continues to demonstrate antimanic, antidepressant, and prophylactic effects in both mania and depression in larger clinical trials, it could prove to be a treatment alternative to currently available therapies in addition to having a different spectrum of both therapeutic effects and side effects.

It is of considerable theoretical interest that the neuroanatomical substrates and biochemical mechanisms involved in carbamazepine's therapeutic effect (44, 45) may differ markedly from those of the other agents routinely used in the treatment of affective illness. Carbamazepine has been demonstrated to suppress after-discharges (68) and spontaneous and induced seizure discharges preferentially in limbic areas over other cortical areas (69–73). It also suppresses seizures kindled in limbic areas by repetitive subthreshold electrical stimulation more readily than those kindled in cortical areas (74–76). Transmission across polysynaptic pathways is depressed by carbamazepine (72, 73, 77–79), especially transmission into limbic areas and from limbic nuclei to diencephalic nuclei (32, 70, 80).

These neurophysiologic actions of carbamazepine could be expected to be efficacious in treating the type of abnormal limbic neuronal sensitization we have postulated to be present in affective illness and psychosis (41–46). Not only would it suppress a potential subcortical limbic focus kindled in amygdala or hippocampus by repetitive stimuli, but it would also be effective in retarding the spread of functional abnormalities to other limbic nuclei or brain regions. It is not known at this point whether these neurophysiologic properties are responsible for carbamazepine's psychotropic effects in affective illness; however, its efficacy does permit and encourage new hypotheses and research into neurobiologic substrates of the affective disorders.

Newborn Minor Physical Anomalies and Problem Behavior at Age Three

BY CHERYL BURG, M.A., A.G.S., JUDITH L. RAPOPORT, M.D., LINDA S. BARTLEY, PATRICIA O. QUINN, M.D., AND PATRICK TIMMINS, M.S.

The authors followed up 136 three-year-olds who had high or low scores for minor physical anomalies of face, head, hands, and feet at birth. Interviews with parents revealed that high-anomaly infants were somewhat more likely to have problem behaviors at age three; this was particularly true for hyperactive-impulsive behavior for boys. Preschool teachers' ratings of hyperactivity, however, did not show a significant relationship to anomaly score. The results suggest some congenital contributors to behavior disorders of childhood, but the relationship between anomalies and problem behavior is weak and limits clinical usefulness of this measure when used alone for identifying a high-risk population.

There has been considerable interest in etiological factors that could explain hyperactive behavior in early childhood. Such factors might help to identify high risk individuals, indicate preventive measures, and help untangle the heterogeneous features of the childhood hyperactivity syndrome.

Recent studies have found an association between the number of minor physical anomalies of hands, feet, head, ears, face, and mouth and behavior and/or learning problems originating in early childhood (1–4). These anomalies are found in children with Down's syndrome but also are associated with other genetic defects and occur within presumably normal populations as well (5).

Quinn and Rapoport (3) reported that hyperactive grade-school-age boys with high anomaly scores (weighted score of 5 or more) were more likely to have had an early onset of hyperactivity (before age three) than were the hyperactive boys in the same study who had a total score of 3 or less. In addition, hyperactive children with high anomaly scores were more likely to have had either a mother who had a history of obstetrical difficulties in this or other pregnancy or a paternal history of hyperactivity. A genotype-phenocopy model was proposed to account for the varied factors that are known to influence the formation of these features in the first trimester of fetal development (5, 6). The finding of more minor physical anomalies in populations of hyperactive children has been replicated by Firestone and coworkers (7, 8), while Campbell and associates (9), Walker (10), and Links and associates (11) have found a higher incidence of anomalies for other behaviorally deviant groups of children. Waldrop and Halverson (2) documented the stability of minor physical anomalies during early and middle childhood and suggested that a measurement of anomalies in newborns may be a useful part of a newborn evaluation to detect infants at risk for later behavioral or developmental deviation. Recently Waldrop and associates (12) reported a significant association between high newborn anomaly scores and nursery school measures of inattentive, hyperactive behavior for 23 boys. Because the findings were based solely on the nursery school observations of a relatively small sample, the question of the clinical usefulness of newborn anomaly score as a predictor of later behavior disorders was not addressed.

In a continuing study (13–16) we examined the newborn minor physical anomaly score and behavior at ages one and two in a subsample of infants selected from a large newborn screening population. An association between high anomaly scores and some "difficult" behaviors was found for both boys and girls. However, there was little consistency in behavioral measures across situations or over time and few significant predictors of behavior problems at age two based on measures from the newborn period or at one year of age. Although the newborn anomaly score did not predict a total score for "problem behavior" at age two, follow-up of this sample to age three was considered important. Behavioral observations at age three were thought more likely to show greater stability across

time and setting, as reported by other investigators (17), and measures at age three were thought to have more clinical relevance than earlier observations (18).

This is a report of the follow-up evaluation of 136 children at three years of age who had been selected in the newborn period on the basis of their minor physical anomaly score. We used a validated behavioral screening interview (18, 19) appropriate for this population and hypothesized that the newborn anomaly score would predict later behavior disorder, particularly hyperactive-impulse disorders in boys.

METHOD

Subjects

From June 1, 1974, to Sept. 1, 1975, all white infants receiving private care in the Georgetown University Hospital newborn nursery were screened for minor physical anomalies using the Waldrop scoring system (1). A total of 933 infants were seen, and interrater reliability for anomaly score was .92. The frequency distribution of these weighted anomaly scores has been reported elsewhere (13).

Mothers of newborns with weighted anomaly scores of 5 or more had been asked to participate in a prospective study of temperament in early childhood. Children with low anomaly scores (a weighted score of 0–3) were enrolled in the study throughout the screening year as a control group. A total of 147 mothers agreed to participate in the study, 73 mothers of high-anomaly and 74 of low-anomaly newborns. The mothers agreed to yearly clinic evaluations of their children through age three. Follow-up sampling at ages one and two are described elsewhere (13, 15).

When the infants were three years old we made a great effort to contact the families of all 147. We were able to contact 136; 108 were available for a clinic visit, and 28 parents were reached by telephone only. Of the 28 parents contacted by telephone, 20 had moved from the immediate vicinity and 8 refused to come in for a clinic visit. The follow-up group of 136 children is 93% of the original sample and the 108 children available for clinic visits is 74% of the initial sample. Of the 136 children followed up, 64 were boys and 72 were girls; 67 had high anomaly scores and 69 had low scores. Of the 108 seen at the clinic, 56 had high and 52 had low anomaly scores.

Procedure

The developmental assessment battery included the Stanford-Binet Intelligence Scale (Form L-M) (20) and the articulation test from the Zimmerman Preschool Language Test (21). An IQ and articulation age were computed for each child. The psychologist (C.B.) used a five-point bipolar scale to make behavioral ratings of attention, activity level, emotional independence, mood, and persistence based on observations during the evaluative session. For these behavior ratings, interrater reliabilities between two of us (C.B. and L.S.B.) were obtained from 24 consecutive evaluations; they were r=.84 for attention, r=.85 for emotional independence, r=.90 for reactivity, r=.76 for mood, and r=.88 for persistence.

We conducted an interview with the accompanying parent using the Richman-Graham interview (22), which was devised for use with the parents of three-year-olds and later used in an epidemiologic survey. This questionnaire obtains information concerning various aspects of development, health, and behavior and has been used to identify children with behavioral difficulties, marked developmental delay, or physical handicaps. An interrater reliability of .95 from 14 consecutive subjects was obtained for this interview during the two-year follow-up assessment (15). Ratings of problem behaviors were obtained from the Behavioral Screening Questionnaire (BSQ) (19), which is comprised of 12 items selected from the Richman-Graham interview (22). These items are eating, sleeping, soiling, activity, concentration, relationships with siblings and peers, dependency and attention seeking, control, tempers, mood, worries, and fears. A score of 10 or above has been found to have considerable validity in identifying mild–moderate problem behaviors (18, 19). Items are scored 0, 1, or 2 and are summed to provide a behavior score.

In addition to the total score, two subscores were obtained from the BSQ. A hyperactivity score was computed from the sum of the six items dealing with activity, concentration, difficulties getting along with peers, being difficult to manage, temper tantrums, and negative mood. A second subscore was obtained for negative-withdrawn behavior from six items dealing with worries, fears, dependency, negative mood, and difficulty concentrating (two items, negative mood and difficulty concentrating were also used for the hyperactivity subscores). We obtained these two scores because the majority of studies on minor anomalies have found the greatest prediction for hyperactive behavior in boys, and one study has suggested that withdrawn, negativistic behavior was associated with high anomaly scores in girls (23).

A subgroup of 29 children was seen during the clinic visit by a child psychiatrist for a half-hour structured play interview. Details of the interview, subsample, and scoring procedures are presented in full elsewhere (24). During the interview ratings were made of the child's ability to separate from parents, numbers of toys touched, and aggressivity in peer doll play.

Of the 136 children in the three-year follow-up group, 90 were enrolled in various preschool programs. For this group, the preschool teachers were requested to rate the child's behavior on the Preschool Behavior Rating Scale (25). We selected the Preschool Behavior Rating Scale because it had been used by Waldrop and associates (12) in their study of newborn

[b]Weighted score of 3 or less.

anomalies and hyperactivity at age three. The scale evaluates children for several dimensions of hyperactive or withdrawn behaviors. The hyperactivity factor is comprised of six scales of hyperactivity: frenetic play, induction of intervention, inability to delay, emotional aggression, nomadic play, and spilling and throwing. The withdrawal factor has three scales: vacant staring, closeness to adult base, and chronic fearfulness. The extreme and intermediate points of each scale are defined and the teacher was instructed to use these points as a basis of judgment to rate the child's behavior from 1 to 11 for each scale. Clinic raters were kept blind to anomaly scores until completion of the study.

RESULTS

The measures of principal interest, Stanford-Binet IQ, the behavior score from the Richman-Graham interview, the hyperactivity and negative-withdrawn subscores from the Behavioral Screening Questionnaire, and the Waldrop preschool hyperactivity and withdrawal scores are given in table 1 for the total follow-up sample divided into high- and low-anomaly groups and broken down by sex. A total of 9 children, or 6.7% of the group, had BSQ scores of 10 or above. The sex and anomaly scores of this group are shown in table 2; 7 children had high anomaly scores, 3 had low scores.

For the total sample, children with high newborn anomaly scores had a slightly but significantly higher total score on the 12-item BSQ. High-anomaly children had a mean score (±SD) of 6.10±2.78, while low-anomaly children had a mean score of 5.10 ±2.37 (χ^2=11.35, df=3, p=.01). Only 1 item discriminated between groups; parents of high-anomaly children reported that their children had difficulties getting along with peers more often than did the parents of low-anomaly children (χ^2=11.37, df=2, p=.003).

TABLE 2
Sex and Newborn Anomaly Scores of Three-Year-Old Children with a Behavioral Screening Questionnaire (BSQ) Score of 10 or Above

Subject Number	Sex	Anomaly Score	BSQ Score
1	F	1	10
2	F	7	10
3	M	2	13
4	F	7	10
5	F	6	12
6	F	5	11
7	M	5	12
8	F	5	10
9	M	1	10

In view of Waldrop's findings (23) of a higher incidence of hyperactive behavior in three-year-old boys who had high newborn anomaly scores and withdrawn behavior in high-anomaly grade-school girls, the relationship between newborn anomaly score and three-year measures was analyzed separately for boys and girls (see table 1). The results for boys were consistent with the findings for the total sample; high-anomaly boys had significantly higher scores on the BSQ (χ^2=7.05, df=1, p<.01) and were also reported to have more difficulties relating to peers (χ^2=8.29, df=2, p=.02). The BSQ score did not differ significantly between high- and low-anomaly girls (χ^2=.21, df=1, n.s.).

The hyperactivity subscore of the BSQ was compared to newborn anomaly score for the total sample and for boys and girls separately. Of the 59 boys, 43 had a weighted newborn anomaly score of 3 or below; 23 of these scored below the median on the hyperactivity scale of the BSQ, and 13 scored above. Of the 26 boys who had high anomaly scores (5 or above), 8 scored below the median on the hyperactivity scale,

and 18 scored above (χ^2=6.62, df=1, p=.01). The association between high newborn anomaly score and hyperactive behavior was highly significant (χ^2=7.76, df=1, p=.0053). This association was not significant, however, for the total sample or for the girls. The negative-withdrawn score showed no significant relationship to anomaly score for girls, boys, or for the sample as a whole.

Newborn anomaly score did not relate significantly to the Binet behavioral ratings, to any of the Nursery School Teacher scale (23) items, or to the hyperactivity or withdrawal factors of the BSQ either for the sample as a whole or for male or female subjects. Because these children did not constitute a clinical sample, we did not have a formal diagnostic category for these children against which to validate behavioral measures. However, the hyperactivity subscore of the BSQ did show significant relationship to independent ratings of hyperactive behavior by the child psychiatrist, psychologist, and teacher. Specifically, this subscore correlated significantly with ratings of "aggression in doll play" (r=.40 p<.05), nursery teacher reports of "induction of intervention" (r=.25, p=.03), and psychologists' ratings of activity and of inattentiveness (r=.23 and .22, respectively, p=.03).

Low but significant correlations were found between similar items across settings. For example, the preschool teacher's rating of hyperactivity correlated significantly with the psychologist's rating of inattentiveness and with parent ratings of "difficulty with peers" and "difficulty in managing" the child. Similarly, children considered withdrawn by the teacher were more likely to be seen as dependent by the psychologist and as less active by the parent, indicating some degree of validity for these ratings.

DISCUSSION

In our follow-up of this sample at ages one and two, newborn minor physical anomaly scores were significantly associated with "difficult" temperamental characteristics reported by mothers and by direct behavioral observations. High-anomaly infants were found to be more difficult at both ages, with greater consistency for males. At age three there were fewer significant associations between the newborn measure of minor physical anomalies and problem behaviors. However, for males significant association between hyperactive impulsive behavior reported by the parent and high newborn anomaly score was consistent. Behavioral ratings by the psychologist during the cognitive assessment and nursery school teachers' ratings, however, were not significantly associated with newborn anomaly scores for the total sample or for boys separately. These findings, therefore, are partially consistent with Waldrop's earlier report (12) of a significant correlation between a high anomaly score at birth and inattentive, hyperactive behavior for boys at three years of age in her research nursery school setting. They do, however, provide some modest support for an association between anomalies and hyperactive-impulsive behaviors seen at home, even for a normal newborn screening sample.

Correlations between ratings of similar behaviors measured in different settings were significant but low. This lack of strong agreement across settings may be accounted for by the variety of ratings, variability in behavior, situational specificity, or differences in parent and teacher attitudes. Such low correlations are also found in studies with older children, however, and are not unique to preschool settings. In fact, the degree of agreement between parents and teachers found here is quite close to that reported for older children (26). It must be stressed, though, that behavioral ratings by 90 different preschool teachers are likely to be of only marginal validity.

In view of the poor agreement about behaviors across settings and across time, "continuous problem cases" were examined; the only 2 children in the group who were consistently reported as difficult at ages one, two, and three were both girls with high newborn anomaly scores. Unfortunately, this small number does not permit clinical generalization.

As a significant proportion of the children in this study were selected on the basis of a high newborn anomaly score, one would have anticipated a higher percentage of children classified as having disordered behavior on the basis of the Richman-Graham interview if newborn anomaly score was a good single predictor of behavior problems at three years of age. However, less than 7% of our group was classified as having disordered behavior based on the Richman-Graham BSQ score, which is consistent with findings reported using this screening instrument for a randomly selected population of three-year-olds (22). The notion of a single biological predictor of behavior and/or learning problems is simplistic; the screening population from which this study sample was selected was not considered to be at high risk because infants from the intensive care nursery were excluded at time of sample selection. If such a high-risk population were examined for minor physical anomalies in the newborn period, it is possible that a high anomaly score combined with other risk factors would be a more meaningful predictor of later developmental difficulties. The intial report of an association between obstetrical problems and newborn physical anomalies for a hyperactive child population suggests that infants from intensive care nurseries or with background risk factors should be screened. One of us (P.O.Q.) has screened patients in a high-risk clinic for minor physical anomalies and is currently investigating whether anomalies predict later developmental problems for such a population (27).

The present study also did not explore the dif-

ferential vulnerability of high- and low-anomaly children to environmental stress. It is possible that infants with a high newborn anomaly score who are subjected to stress from an unfavorable environment may be more likely to develop behavioral problems of clinical significance. Such an interaction between biological and environmental influences has been shown by Werner and coworkers (28).

Our study differed from Waldrop's in that ratings of the nursery school behavior were obtained from the teacher of the program in which the child was currently enrolled. Therefore, both the lack of uniformity in settings and the likelihood of differences in the teachers' ability to assess behavior were likely to decrease the reliability and validity of the nursery school ratings. It would have been beneficial to have confirmation of the teachers' ratings by an independent observer. Waldrop and associates (12) found a significant association between newborn anomaly scores and inattentive, hyperactive behavior in a research nursery school for 23 boys. However, all the children in Waldrop's study attended a research nursery school so that there were controls for both setting and observers. In addition, multiple observations were made for each child, and data from a mechanical activity recorder were used. Finally, because only 90 children attended preschool and it is possible that some, more deviant children were not considered ready for school, the preschool study sample may be biased; for example, Richman (18) found language-delayed children were less likely to have been enrolled in preschool.

Behavioral ratings by the clinic psychologist were carried out in a one-to-one novel setting. Although these ratings were reliable and made by the same observer, it is possible that in this situation the children were more likely to be calmer and more attentive than in a naturalistic setting.

Our methods of behavioral evaluation lack the technique of some more intensive studies, which are more feasible with small samples. Walzer and associates (29), for example, after studying young children with sex chromosome abnormalities, reported a method for the longitudinal study of behavioral development in infants and children that used blind observers to confirm data obtained from structured interview or from parent report, in which interviewer bias or the distortions of an untrained observer may have been introduced. On the other hand, our approach did approximate the naturalistic clinical setting.

Firestone and associates (8) studied minor physical anomalies in hyperactive, retarded, and normal control children and their families. Their findings suggest that if an anomaly score alone was used as a marker in the early detection of problem children, the number of false positives in a single family would be very high. Our findings in children at three years of age support this point. In spite of some associations between newborn anomaly score and behavioral problems, newborn anomalies are not acceptable as clinical predictors of behavior problems, because many false positives (as well as some false negatives) would be identified.

Although the correlations between high anomaly score and parents' reports of difficult behaviors are of considerable interest, interpretation of this association remains difficult because these effects may be mediated by environmental factors. For example, high-anomaly infants might have high-anomaly mothers who in turn could be irritable; poor maternal rapport could produce these differences in infant behavior. Alternately, a high-anomaly father could create a disturbed home environment that disturbs the mother and/or child. Further studies on the epidemiology and behavioral correlates of minor physical anomalies should include parental anomaly and temperament ratings as well as a more traditional clinical assessment of family setting.

Foundations' Fund Fellowships for Sabbatical Research in Psychiatry and Its Basic Sciences

The Foundations' Fund for Research in Psychiatry conducts a limited program of support for scholars on sabbatical leave in order to further their research and contribute to the knowledge of psychiatric diagnosis, treatment, and prevention. The sabbatical must be spent away from the home institution at an internationally recognized institution.

Applications are open to creative investigators with demonstrated research contributions in the field who hold full-time positions in professional schools and graduate departments of universities or equivalent institutes of research. Applicants must be U.S. or Canadian citizens or permanent residents.

The deadline for receipt of applications is August 1, 1980, for sabbaticals beginning July 1, 1981, or later.

Information may be obtained from:

The Case of Anna O.: A Reformulation

BY MARC H. HOLLENDER, M.D.

The best known of all psychotherapy patients, Anna O., entered treatment with Josef Breuer in December 1880. Modern psychotherapy begins with that encounter. Information gathered in the intervening years places us in a favorable position to review and reformulate the case. To do so may have practical and theoretical, as well as historical, importance.

After the passing of a century, one in which much has been learned about psychotherapy, we are in a favorable position to review and reformulate the germinal case of Fraulein Anna O. For our purposes, three rich strands of data are available: 1) Breuer's account of the illness and treatment of the patient, an account more detailed than was customary at the time but sketchy by present-day standards, 2) biographical information about the later life and work of Anna O. (Bertha Pappenheim), and 3) biographical information about the therapist, Josef Breuer.

ANNA O.'S ILLNESS

Anna O. had nursed her father, who was dying of a "peripleuritic abscess" (presumably tuberculosis), for six months before she became incapacitated. Breuer (1) stated,

> During the first months of the [father's] illness Anna devoted her whole energy to nursing her father, and no one was much surprised when by degrees her own health greatly deteriorated. No one, perhaps not even the patient herself, knew what was happening to her; but eventually the state of weakness, anemia and distaste for food became so bad that to her great sorrow she was no longer allowed to continue nursing the patient. The immediate cause of this was a very severe cough . . . a typical *tussis nervosa*. (p. 23)

Breuer was called because of the cough, but he quickly perceived that much more than the cough required his attention.

To treat each of a myriad of symptoms, the patient herself devised a procedure she referred to, when speaking seriously, as a "talking cure" and jokingly as "chimney-sweeping." It soon became evident to her physician that

> every one of the spontaneous products of her imagination and every event which had been assimilated by the pathological part of her mind persisted as a psychical stimulus until it had been narrated in her hypnosis, after which it completely ceased to operate. (1, p. 32)

Breuer (1) also stated that "complexes were disposed of by being given verbal expression during hypnosis."

TREATMENT OF THE SYMPTOMS

How did Anna O. happen to invent the talking treatment that has come to be known as "Breuer's Cathartic Method"? We do not know for certain, but there are some clues. It seems likely that she was influenced by Jacob Bernay's book on the Aristotelian concept of catharsis, which was published in 1880. According to Ellenberger (2), the book, which was discussed by scholars and became a topic of conversation in Viennese salons, stimulated a widespread interest in catharsis. Thus, it is likely that Anna O. was introduced to catharsis as a method and then put it to use as a means of capturing and holding the attention of her scientifically minded physician. If such was her conscious or unconscious purpose, she succeeded admirably.

We might now ask: Is the talking cure effective and, if so, how does it work? Breuer (1) stated that "each symptom disappeared after she [Anna O.] had described its first occurrence." To explain this phenomenon, Freud (3) postulated that "the illness occurred because the affects generated in the pathogenic situations had their normal outlet blocked." As a result, the "'strangulated' affects were then put to an abnormal use." Freud added,

> In part they remained as a permanent burden upon the patient's mental life and a source of constant excitation

for it; and in part they underwent a transformation into unusual somatic innervations and inhibitions, which manifested themselves as the physical symptoms of the case. For this latter process we coined the term "hysterical conversion." (p. 18)

The schema used to explain the response to the cathartic method involves a hydraulic model. When a closed valve, producing a reaction (symptom), is released (by catharsis and abreaction), pressure is dissipated and a normal state reestablished. However, clinical experience tells us that catharsis and abreaction by themselves are effective only in grief reactions and perhaps traumatic neuroses, and then merely to a limited extent. They are not usually effective in treating hysterical symptoms. Ellenberger (2) came to the conclusion that "the famed 'prototype of a cathartic cure' was neither a cure nor a catharsis." Breuer (1) himself acknowledged that the disappearance of symptoms after being talked away might very well "be explained by suggestion."

It may be, however, that the talking cure did work but that it actually consisted of more than catharsis and abreaction. In the process of talking, Anna O. converted a nonverbal message, expressed in pantomime or body language and called a hysterical symptom, into verbal language. In other words, in her free associations Anna O. converted or translated her message from one language into another. Once she expressed herself directly and openly, she no longer had need for indirect and disguised communication (the so-called symptom).

It is noteworthy that Breuer's treatment of Anna O. at a time when she was not using the talking cure involved decoding the content of a hysterical symptom, interpreting its meaning, and overcoming a blockage by obliging the patient to talk about the inhibiting factor. Breuer (1) presented the following account:

> For two weeks she [Anna O.] became completely dumb and in spite of making great and continuous efforts to speak she was unable to say a syllable. And now for the first time the psychical mechanism of the disorder became clear. As I knew, she had felt very offended over something and had determined not to speak about it. When I guessed this and obliged her to talk about it, the inhibition, which had made any other kind of utterance impossible as well, disappeared. (p. 25)

NATURE OF THE "ILLNESS"

Breuer and Freud's formulation of Anna O.'s disorder was essentially symptom-oriented, intrapsychic, and psychobiological. The formulation that I will now propose is essentially person-oriented, interpersonal, and psychosocial.

The nature of a major problem faced by Anna O. was described in the first paragraph of the case history. Breuer (1) stated,

> She [Anna O.] was markedly intelligent, with an astonishingly quick grasp of things and penetrating intuition. She possessed a powerful intellect which would have been capable of digesting solid mental pabulum and which stood in need of it—though without receiving it after she had left school. (p. 21)

Anna O., a bright and lively person, lived at the wrong time and in the wrong place. A woman's opportunities for a professional career in nineteenth century central Europe were extremely limited. As Ellenberger (2) pointed out, the universities were still closed to women. Consequently, Anna O.'s situation was a "contrast between the ambitions and the obstacles set to ambitions." Her plight was compounded by the fact that she was a daughter in an Orthodox Jewish family, in which sons traditionally were accorded preferential treatment. Schooling for Anna O. ended when she was 16. Her brother, who was approximately one and one-half years younger and possessed neither her intellect nor her talent, was afforded educational opportunities closed to her and became a lawyer.

Not only was Anna O., as a female, relegated to an inferior position in her family with future prospects limited to that of becoming a wife and mother, but at the age of 21 she was suddenly called on to assume the onerous chore of nursing her father.

After describing the nature of Anna O.'s problem as a woman in Vienna in 1880, Breuer (1) mentioned the manner in which she tried to cope with it:

> This girl, who was bubbling over with intellectual vitality, led an extremely monotonous existence in her puritanically-minded family. She embellished her life . . . by indulging in systematic day-dreaming, which she described as her "private theatre." (p. 22)

Breuer quickly recognized the nature of Anna O.'s plight, but evidently he did not as quickly become aware of how fascinated he was by his bright, attractive, and personable patient. Jones (4) pointed out, "In those days, to devote hours every day for more than a year to a single patient, and an hysteric at that, signified very special qualities of patience, interest, and insight." Perhaps the words "personal involvement" should be substituted for "insight." While Breuer and Anna O. focused on her symptoms, a relationship developed between them, based on intellectual and sexual attraction, that might aptly be characterized as mutual infatuation.

As Pollock (5) has suggested, a special circumstance may have played a substantial part in drawing Breuer to Anna O. She may have evoked a profound reaction in him by rekindling repressed longings for his mother, who had died "in the blossom of her youth and beauty" when he was between 3 and 4 years of age. The mother, as remembered by her son, and Anna O. may have been alike in many respects. Perhaps the early "imprinting" of an image, unconscious and indelible,

was at work. Whatever the roots—and the reactivation of feelings about the therapist's mother would certainly be important—the relationship between physician and patient became intense and engrossing.

Breuer's fascination must have been evident to Anna O. not only because of the time he devoted to her care but also because of the nature of the attentions he showed her. Clearly, his interest went well beyond defining the cause of her symptoms and curing them, although the treatment of these symptoms superficially remained the currency used in their interpersonal exchange.

Anna O., in turn, was in all likelihood captivated by Breuer. Instead of taking refuge almost exclusively in her "private theatre," she had his company to help relieve the tedium and boredom of her confined life. The myriad of symptoms she developed justified constant medical attention and absolved her of guilt for withdrawing from nursing her dying father. The form of treatment she invented was well designed to keep her physician engaged and to make him hopeful of achieving a complete cure.

It is noteworthy that Anna O. would engage in the symptom-relieving treatment only with Breuer. He stated (1) that while he was away on vacation "no 'talking cure' had been carried out, for it was impossible to persuade her to confide what she had to say to anyone but me." On returning from vacation, he found his patient "in a wretched moral state, inert, unamenable, ill-tempered, even malicious." Failing to recognize that she was angry at him for leaving (deserting) her, he attributed her reaction to a "physical stimulus" that had not been discharged. He arranged for her to be brought back to Vienna from the country for a week so that she could tell him three to five stories each evening. This special attention was effective, but Breuer attributed the change in the patient to her narrations under hypnosis. Breuer continued to focus on the effect produced by catharsis, while the influence of the relationship between patient and physician went unnoticed.

Anna O.'s relationship to Breuer also became clear in his description of events that occurred shortly after her father's death (1).

> I was the only person whom she always recognized when I came in; so long as I was talking to her she was always in contact with things and lively. . . . She had eaten extremely little previously, but now she refused nourishment altogether. However, she allowed me to feed her, so that she very soon began to take more food. (pp. 26, 27)

At no point did the nature of the relationship between Anna O. and Breuer become clearer than at the time of the termination of treatment. According to Strachey (6), "The patient suddenly made manifest to Breuer the presence of a strong unanalyzed positive transference of an unmistakably sexual nature." This young woman in whom it was said "the element of sexuality was astonishingly undeveloped" (1) was seen to be, as Jones (4) described it, "in the throes of an hysterical childbirth [pseudocyesis], the logical termination of a phantom pregnancy that had been invisibly developing in response to Breuer's ministrations."

Freud (7) in writing about the event in a letter to Stefan Zweig, stated,

> On the evening of the day when all her [Anna O.'s] symptoms had been disposed of, he [Breuer] was summoned to the patient again, found her confused and writhing in abdominal cramps. Asked what was wrong with her, she replied: "Now Dr. B's child is coming!". . . . Seized by conventional horror he took flight and abandoned the patient to a colleague. For months afterwards she struggled to regain her health in a sanatorium. (pp. 412–413)

The evidence seems conclusive that Anna O., unbeknown to her physician, had continued to daydream—to hold performances in her "private theatre." There was, however, an important change in the cast; her physician now played the male lead.

ANNA O.'S SOLUTION

Breuer (1) noted that Anna O., even during her illness, "was greatly assisted by being able to look after a number of poor, sick people, for she was thus able to satisfy a powerful instinct." In 1895 Bertha Pappenheim accepted a position well suited to her talents and her emotional needs; she became the housemother of a Jewish orphanage in Frankfurt-am-Main (8). No longer did she have to live her life largely in fantasy. The woman who had been placed in an unacceptable position as a female could now turn her energies to the care of children and campaign for the rights of women. Had she not found these outlets for her strength, ideas, and gifts, she might have fallen ill again (9).

Not only did Bertha Pappenheim's work, at first with orphans and later with wayward girls, bring her to the fore as a social worker, but her writings marked her as a feminist leader. In 1899 she translated Mary Wollstonecraft's book, *A Vindication of the Rights of Women* (1792), from English into German. The book was a plea for the education of women. In writing about the Jewish problem in Galicia the following year, her chief point was that "the intellectual education of girls was being neglected" (8).

In 1899 Bertha Pappenheim wrote a soap opera-style but revealing play entitled "Women's Rights." As Karpe (10) noted, the play focused on the political, economic, and sexual exploitation of women. In the third and final act, a lawyer's wife persuades her husband to accompany her to the apartment of a poor, sick woman. As they enter the apartment, the dying woman rec-

ognizes the lawyer as her former lover, who deserted her when she became pregnant. His shocked wife tells him that because of their children she will not leave him, but that from now on she will refuse marital relations as "her woman's right." Is a theme repeated? Was this poor woman, deserted by her lover when she became pregnant, really Anna O., who, when pregnant (pseudocyesis), was deserted by Breuer?[1]

COMMENT

Limited opportunities existed in central Europe before the turn of the century for women of talent like Anna O. Her aspirations, if expressed, were not likely to be accorded a sympathetic reception. It is little wonder that she turned to fantasy. Such was her chief outlet at the time when her father became ill and, in keeping with the prevailing custom, she was called on to nurse him. For six months she cared for him before the tedium of her life as a woman and the ambivalence of her feelings toward her father as a man led to incapacitating hysterical symptoms. (Her lot must have been especially difficult to bear as she watched her brother continue his schooling.)

The intimate relationship Anna O. developed with her physician filled a void in her life. His attentions and her elaboration on them in fantasy were, in all likelihood, the basis of her response to treatment. Although it is likely that some symptoms were dispelled by catharsis and abreaction, it is unlikely that the release of dammed up or strangulated affects can explain the favorable response. It is safe to state that the nature of her relationship to Breuer was fundamental and that the dissolution of the relationship left her once again without an outlet for her pent-up feelings. Within five weeks a recurrence of symptoms required treatment, and this time she was admitted to a sanitarium, where she remained for several months (2).

Little is known about Anna O.'s life during the period between 1883 and 1895. Beginning in 1895 when she took on the role of housemother to an orphanage, she succeeded in sublimating her feelings in her work and her writings. She at last found an outlet for her talents and a cause to which she could dedicate herself.

Ellenberger (2) described the transition from the incapacitated patient, Anna O., to the effective and successful social worker and feminist, Bertha Pappenheim, as follows:

> Anna O.'s illness was the desperate struggle of an unsatisfied young woman who found no outlets for her physical and mental energies, nor for her idealistic strivings. It needed much time and effort before she succeeded in sublimating her personality into the respectable figure of a pioneer of social work, fighter for the rights of women and the welfare of her people—Bertha Pappenheim.

What role did Anna O. play in the development of modern psychotherapy? Before the invention of the talking cure, hypnosis was used mainly for suggestion and the physician was a doer. With the shift to catharsis, the physician became a listener. This step may seem trivial today, but in its time it was monumental. As a result of it, Breuer could state that his patient's life became known to him to an extent to which one person's life is seldom known to another. It also shifted the focus from biology to psychology. Instead of asking what caused the *disease* labeled hysteria, the physician now asked about the emotional antecedents of the disorder (11). Thus, Breuer's treatment of Anna O. started us on the road that would lead to definitive forms of psychotherapy. It led the way, too, to the giant steps taken by Breuer's young friend, who was so profoundly impressed when he heard about this remarkable case.

[1]This connection was suggested to me by Jane R. Weinberg, M.D.

Relapse in Schizophrenia

BY MARVIN I. HERZ, M.D., AND CHARLES MELVILLE, PH.D.

Although schizophrenia is a chronic illness with exacerbations and remissions, there has been surprisingly little systematic study of early signs of relapse. The authors gave 145 chronic schizophrenic patients and 80 family members a structured interview regarding early signs of relapse and other information related to the relapse period. Most patients and family informants were aware of a prodromal period during which patients experienced such symptoms as having trouble sleeping, having trouble concentrating, loss of appetite, and feeling depressed. The authors discuss the implications of these findings for the treatment of chronic schizophrenic patients.

Although schizophrenia is a chronic illness often characterized by exacerbations and remissions, there has been surprisingly little systematic study of early signs of relapse and the decompensation process. In contrast, there has been a great deal of investigation of the early warning signs of dyscontrol of chronic physical illnesses, such as diabetes; it would be unheard of for physicians not to alert patients and family members to these early danger signals so that the development of serious complications can be prevented. Psychiatry may not have addressed the question of relapse in schizophrenia because in the past most patients were housed in custodial institutions and little attention was paid to fluctuations in the course of the illness. Most patients now live in the community and are visible when they relapse, especially if they become aggressive or disruptive and require rehospitalization. This paper will describe the results of a survey of 145 patients and 80 family informants who were interviewed about early signs of relapse and other information related to the relapse period.

Presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12-18, 1979. Received June 22, 1979; revised Dec. 26, 1979; accepted Feb. 11, 1980.

The impetus for this study came as a result of our interest in finding ways to diminish the incidence of untoward side effects related to prolonged use of maintenance antipsychotic medication. Hogarty and associates (1) conducted a large scale study of the effects of antipsychotic agents and concluded that drugs administered during the aftercare phase of schizophrenia do not reduce symptoms but are prophylactic, i.e., raise the patient's threshold for further episodes. Hogarty and associates found that patients on medication who were later given placebo did not have a steady downhill course. Instead, most remained in remission, and their symptom patterns and severity, measured cross-sectionally, were similar to those of the drug patients; however, many of the placebo patients suddenly relapsed at some point during the 2 years of the study and had to be hospitalized or removed from the study in order to receive active drug treatment. If the major effect of antipsychotic drugs is prophylactic for most patients, perhaps drugs should be given only at the point of early relapse rather than on a maintenance schedule.

Studying early signs of relapse not only provides guidelines for initiation of medication for patients but helps psychiatrists to determine when medication should be increased in patients already on maintenance therapy. Many patients who take active drugs also relapse. Davis and associates (2) found in 23 controlled studies 20% of patients taking active drugs relapsed compared with 52% taking placebo. In order to deal with the issue of drug noncompliance, Hogarty and associates (3) compared schizophrenic patients taking oral fluphenazine with those taking intramuscular fluphenazine and found a relapse rate approaching 40% in both groups by the end of 1 year. The fact that patients relapse regardless of maintenance medication indicates a definite need to study early signs of relapse.

Our search of the literature revealed little data regarding early signs of relapse in schizophrenia or the length of the prodromal period. The length of the prodromal period is important if efforts at early intervention to prevent full relapse are to be successful. Docherty and associates (4), who recently reviewed the literature on stages of onset of schizophrenic psychosis, stated that despite its obvious importance, there are very few hard data available on the decompensation process. Most studies have been carried out by gifted clinicians whose usual approach is a detailed

case study, in which information is gathered retrospectively from patients and family members. Donlon and Blacker (5) took a different approach; they interviewed schizophrenic patients who were being withdrawn from medication and were beginning to relapse. Their observations, however, did not involve systematic ratings and their data were reported anecdotally. In their review Docherty and associates (4) stated that despite the different methods used to study the question, there was a concordance in the descriptions of identifiable premonitory signs as well as of regular and sequential unfolding of psychological states before psychotic breakdown. They differentiated five stages in schizophrenic decompensation, the first two stages of which are nonpsychotic:

1. *Overextension*. During this phase the person begins to experience a sense of being overwhelmed.
2. *Restricted consciousness*. During this phase a variety of mental phenomena appear that seem to bring about a limitation of the person's range of thought.
3. *Disinhibition*. During this phase relatively unmodulated impulse expression appears. This period may bear a close resemblance to hypomania.
4. *Psychotic disorganization*. The three subphases are destructuring of the external world (with increasing perceptual and cognitive disorganization), destructuring of self (with loss of self-identity), and total fragmentation (with complete loss of self and control).
5. *Psychotic resolution*. Less anxiety and psychotic reorganization, either of a delusional system or massive denial of unpleasant affect and responsibility.

METHOD

Since the literature is largely anecdotal, we decided to study systematically a large sample of patients from two locations over a 2-year period. In Atlanta (group A) outpatients (N=99) and family informants (N=80) at two community mental health centers were interviewed. Later, in an attempt to obtain data closer to the time of relapse we added group B, which included 46 hospitalized patients in Buffalo who had recently experienced a psychotic episode.

All patients were diagnosed as schizophrenic according to *DSM-II* and had no secondary diagnosis. The outpatients were being maintained on antipsychotic medication at the time of interview. Most patients had been hospitalized at least two or three times. At the time of the study, outpatients were considered to be functioning at a stable level and inpatients had recompensated sufficiently to cooperate with the research interviewer.

We collected demographic information from both groups. Group A was primarily suburban or rural and white; 67% were women and 33% were men. Their average age was 38 years and their average level of education was 9.8 years. The level of employment was low—only 15% were employed and 85% were unemployed. Only 33% were married, 21% were divorced or separated, 6% were widowed, and 40% had never been married. Approximately 73% had been hospitalized three or more times.

Group B was largely urban. Of the 46 patients, 70% were women and 30% were men; 68% were white, 28% black, and 4% Puerto Rican. Their average age was 38 years and average level of education was 9.2 years. The level of employment was somewhat higher than that of group A—26% were employed, 67.5% were unemployed, and for 6.5% data were unavailable. Most patients were unmarried: 23.9% were married, 30.4% were divorced or separated, 6.5% were widowed, 37% had never been married, and for 2.2% data were unavailable. Information on patients' living arrangements was collected only from group B. Only 17% lived alone, 70% lived with either a spouse, child, or parents, and 9% lived in a supervised facility; for 4% information was unavailable. More than half of the patients in group B were involuntary hospital admissions.

We constructed a structured interview, with a few open-ended questions, based on items contained in the Psychiatric Status Schedule (6), Research Diagnostic Criteria (7), and on clinical experience. The questionnaire, modified in Buffalo on the basis of experience gained during the Atlanta study, contained 52 items describing symptoms and feelings and other questions relevant to the period of relapse. An interview normally lasted from 30 to 45 minutes.

Each patient was interviewed individually by a research member of the staff, after being asked if he or she was willing to answer questions about his or her illness. The patient was informed that the information obtained would be included in the patient's chart and used in treatment planning. The same interview was conducted with available family members. In Buffalo the relative sample was very small because of difficulties arranging appointments; therefore, these data are not included and family data are reported for the Atlanta group only.

RESULTS

In response to the question, "Could you tell that there were any changes in your thoughts, feelings, or behaviors that might have led you to believe you were becoming sick and might have to go to the hospital?" approximately 70% of patients in both groups noticed changes and 30% did not. Families were much more likely to notice changes in the patients (92.6%) than were the patients themselves. In about 66% of the cases, the patient and the family informant agreed that there were recognizable early signs of decompensation, indicating a high level of concordance.

The time interval between the beginning of symp-

TABLE 1
Time Between Perception of Symptoms and Hospitalization in Schizophrenic Patients

Time	Buffalo Group (N=46)		Atlanta Group			
			Patients (N=99)		Families (N=80)	
	N	%	N	%	N	%
<1 day	3	6.5	8	8.1	9	11.2
1-3 days	7	15.2	8	8.1	6	7.5
4 days-1 week	4	8.7	14	14.1	7	8.8
1-2 weeks	1	2.2	8	8.1	16	20.0
2-4 weeks	9	19.6	16	16.2	3	3.7
>1 month	14	30.4	23	23.2	35	43.8
Unknown	8	17.4	22	22.2	4	5.0

toms and the need for hospitalization is extremely important if medication and crisis intervention techniques are to be used to help prevent full relapse. According to the results of our interviews (table 1), only 7%–8% of patients and 11% of family members stated that the time period was less than 1 day. Approximately 15% of group B patients and 8% of group A patients and their families noticed a prodromal period of only 1–3 days. Most of the patients and family members, however, said that it takes more than a week—52% of group B patients, 48% of group A patients, and 68% of group A families. Thus, for most patients, relapse is not abrupt and sudden, and it is possible to institute effective crisis treatment to prevent full relapse.

When asked, "What did you do about these changes when you realized that they might become serious?" almost 50% of patients responded that they sought professional help and 60% of the relatives said that they arranged for professional help for the patient. Approximately 33% of group B patients and 26% of group A patients reported that they did nothing. Since antipsychotic medication is especially effective in treating acute symptoms, it is disconcerting that less than 4% of all patients and family members said that patients took more medication when they realized that symptoms were becoming serious.

Approximately 24% (N=24) of group A patients and 33% (N=15) of group B patients claimed that no medication had been prescribed for them, but it is possible that some of them chose simply to ignore their prescriptions. Only 26% of group B patients (N=12) and 50% of group A (N=49) patients stated that they were taking medication as prescribed. The primary reason given by patients for not taking medication as prescribed was that it did not help (group A, N=12; group B, N=6). The next most commonly mentioned reason was that it had unpleasant side effects (group A, N=2; group B, N=6). If withdrawal of medication does not affect symptoms adversely for most stabilized patients, they might conclude that the medication was not helping and therefore was not necessary. In fact, there are reports of an increased energy level and sense of well being when medication is terminated (8). For some patients this may be due to an amelioration of an unrecognized extrapyramidal side effect, akinesia (9, 10).

We assessed the importance of precipitating events by asking patients if anything occurred in their lives that might have led them to become upset. Approximately 40% of the patients and family members did not know of any such event or believed that biological factors were responsible. Approximately 33% of the patients and relatives were able to relate the most recent episode to a stressful life event such as loss of a significant other, loss of a job, marital problems, etc. Only about 2% of patients attributed relapse to stopping or incorrectly using their medication. Other reasons given by patients and relatives were taking alcohol or drugs and feeling socially isolated. Davis and associates (11) reported that a large number of patients are not aware of a precipitating life event; however, a prospective study conducted during time of early relapse might reveal events important to the patient that are later denied, repressed, overlooked, or forgotten, such as changes in the emotional climate of the family along dimensions described by Vaughn and Leff (12). Patients are liable to relapse when there is a good deal of criticism or overprotectiveness by family members.

What were the symptoms that either appeared for the first time or worsened in the prodromal period before full relapse and hospitalization? The Atlanta patients were outpatients in a relatively stable condition and the Buffalo patients had recently been hospitalized and were recovering from an acute episode. In spite of these and other differences between the two groups, the rank-order correlation of symptoms that appeared or worsened before hospitalization between the Buffalo and Atlanta patients was .85 ($p<.001$) (table 2). Becoming tense and nervous was the symptom reported by most patients in both groups. Generally, the symptoms most frequently mentioned by patients and family members were symptoms of dysphoria that nonpsychotic individuals experience under stress, such as eating less, having trouble concentrating, having trouble sleeping, depression, and seeing friends less. Among the first 10 most commonly noted psychotic symptoms were feelings of being laughed at or talked about and possibly increased religious thinking.

The rank-order correlation of frequency of symptoms reported by Atlanta patients and their relatives was also very high ($r=.78$, $p<.001$). Some relatives who were sensitive to the patients might notice dysphoric signs before the patient did, although insensitive relatives who were not in touch with the patient's feelings or behavior might tend not to notice early symptoms and rate more extreme psychopathology high. The only psychotic symptom for which there seemed to be a large degree of disagreement was talking in a nonsensical way, which was ranked 3rd by families and 13th by patients. Relatives ranked hearing voices and seeing things 10th and

TABLE 2
Symptoms That Appeared or Worsened Before Hospitalization in Schizophrenic Patients[a]

	Buffalo Group (N=46)		Atlanta Group			
			Patients (N=99)		Families (N=80)

Drinking more, using drugs	29	21.7	28	20.2	28	25.0

[a]Spearman rank-order correlation for Buffalo patients and Atlanta patients = .85 and for Atlanta patients and families = .78 ($p<.001$).

patients ranked it 17th. These differences could also be related to patients' denial of psychotic symptoms.

When patients were asked, "What were the first changes in thoughts, feelings, or behavior that might have led you to believe that you were becoming sick and might have to go to the hospital?" there was little agreement. Among the symptoms mentioned were tension, anxiety, nervousness, insomnia, and depression. Hearing voices was mentioned by 5 group B patients and 8 group A patients as the first change noticed.

When asked whether the pattern of development of symptoms was similar for each episode, 50% of the patients answered "yes" and 50% answered "no." Whether or not individual patients have the same sequential pattern of symptoms each time they relapse is of great importance to the psychiatrist who plans the treatment strategy.

Only Buffalo patients were asked, "Can you tell me which of the following symptoms are present when you are feeling well?" Sixty percent stated that they had feelings of loneliness. This seems high considering that many of these patients lived with a relative. A large number of neurotic symptoms, such as tension and nervousness, feeling sad or blue, and worrying were reported by 48% of patients. A fewer number of psychotic symptoms, such as thought broadcast (reported by 30%) and hearing voices (reported by 26%), were reported during a state of presumed stability. Astrachan and associates (13) reported similar findings after interviewing schizophrenic patients 2–3 years after hospital discharge.

CONCLUSIONS

Creer and Wing in England (14) took a survey of 80 relatives of schizophrenic patients which revealed that virtually none of the relatives had received any sensible advice about the nature of the condition, about how to supervise medication, about the likely outcome of treatment, or about how to best respond to disturbed or disturbing behavior. Usually when a family member has a chronic physical disability, such as paraplegia or renal failure, management is worked out in detail and patients and relatives are taught to predict and prevent many problems and to know what to do in time of crisis. We recommend that the treatment of every schizophrenic patient include a major focus on teaching the patient and family not only to recognize early signs of decompensation but also what steps to take to ensure the initiation of prompt and effective treatment. Because the prodromal period usually lasts

more than a few days, it should be possible to abort an incipient acute psychotic episode. It may even be possible in some well-stabilized patients who are cooperative in treatment to use antipsychotic medication only when there are early signs of relapse rather than the usual practice of maintaining such patients on drugs indefinitely. In either case, patients and families should be educated about the special value of antipsychotic medication during the relapse period.

Our finding that there is usually a nonpsychotic prodromal period confirms Docherty and associates' results (4). Our patients, however, did not report two distinct stages of symptoms during the prepsychotic phase of relapse described by Docherty and associates. Whether these prepsychotic stages have general validity could be determined from prospective studies while the symptomatology is unfolding. It may be that for the usual chronic schizophrenic patient who has little insight these stages are not recognizable. Further research is needed in order to differentiate when the appearance of nonpsychotic symptoms signals an impending relapse and when it does not.

Our data on relapse in schizophrenic patients are based only on retrospective reports by patients and families; however, the data reported by Atlanta patients and their families were later substantiated by reports from a second sample of patients in Buffalo. Future research in this area should be prospective rather than retrospective and should use patient and family interviews as well as psychophysiological and biochemical measures.

Male Rape: Offenders and Victims

BY A. NICHOLAS GROTH, PH.D., AND ANN WOLBERT BURGESS, R.N., D.N.SC.

In an analysis of 22 cases of male rape in a community setting, the gender of the victim did not appear to be of primary importance to some of the rapists, but for others, males appeared to be specific intended targets, and the rapists' assaults were an effort to deal with unresolved and conflictual aspects of their lives. For all offenders the sexual assault was an act of retaliation, an expression of power, and an assertion of their strength and manhood. The impact of rape on the male victims was similar to that on female victims, disrupting their biopsychosocial functioning; however, male rape appears to be underreported due to the stigma associated with it.

Although the professional literature has increasingly focused on the clinical dynamics of rapists (1, 2) and the trauma of victims (3, 4), investigators have almost exclusively studied offenses committed against women and children. Except for a few articles on the sexual assault of male inmates in a prison setting (5, 6), little attention has been given to the forcible sexual assault of adult males (7).

Police statistics would appear to support this impression. For example, in Boston in 1976, of 355 reported rapes, only 4 male victims (1%) were 17 years or older.[1] In addition, a survey of the Philadelphia Women Organized Against Rape crisis center revealed that of the 382 client contacts over an 8-month period in 1977, 22 (6%) of the victims were male, but of these only 1 (0.3%) was over the age of 16.[2]

In our clinical work we have had access to a number of male offenders who raped adult males or male agemates and to a number of male victims of sexual assault. Although we are reporting on a small sample and thus cannot generalize any findings, we believe the data provide observations of interest to professionals. This paper focuses on 1) descriptive characteristics of the offense, the dynamics of the offender, and the impact on the victim, and 2) similarities and differences between male and female rape.

METHOD

Data were obtained from a total of 22 subjects—16 males who admitted having sexually assaulted other males and 6 additonal males who identified themselves as victims of rape. The rapists were convicted offenders referred for evaluation to the Center for the Diagnosis and Treatment of Sexually Dangerous Persons in Bridgewater, Mass.; the Whiting Forensic Institute in Middletown, Conn.; the Harrington Hospital Forensic Mental Health Program in Southbridge, Mass.; or the Connecticut Correctional Institution in Somers, Conn. The victims were either self-referred or referred to us by police or hospital personnel. None of the offenders was convicted of the sexual assault. This study's offender and victim samples, then, were independent and unrelated.

Information about the nature of the offenses, the dynamics of the assailants, and the reactions of the victims was retrieved and recorded through interviews with the subjects. In addition, their available clinical records were examined. Informed consent was obtained from all of the subjects, and none refused to participate in this investigative study.

Characteristics of the Offenders

The offenders ranged in age from 12 to 41 years. Three were juveniles between the ages of 12 and 16, and the majority (N=13; 81%) were young adult males; the average age was 24. These 16 offenders sexually assaulted a total of 24 victims, who ranged in age from 10 to 30 (average age=17½).

Most of the offenders (N=13; 81%) and their victims (N=23; 96%) were white. Three offenders and 1 victim were black. Only 2 assaults, involving a black offender and a white victim, were interracial.

The majority of the offenders (N=12; 75%) were total strangers to their victims. Three of the offenders knew the victims casually, and 1 offender was the vic-

tim's brother. Four offenders had codefendants; the other 12 had acted alone.

At the time of their offense all of the men in the offender sample were actively engaged in consenting sexual encounters or relationships. Eight men (50%), 4 of whom were married, confined their consenting sexual activity to members of the opposite sex. Six offenders (38%), 2 of whom were married, engaged in consenting sexual encounters with both men and women; 3 of these men were extremely conflicted over their sexual encounters with other males. Two of the men in this sample confined their consenting sexual encounters almost exclusively to other men, but neither was committed to a permanent relationship.

Characteristics of the Victims

The 6 victims interviewed in this study ranged in age from 16 to 28 years (average age=17½ years). They were raped by men ranging in age from 16 to 30 years (average age=22 years). All of the victims were white, as were all but 1 of their assailants. Half of these subjects were sexually assaulted by strangers. One was raped by a casual acquaintance, and 2 by close friends (in one case the offender was a classmate; in the other he was the victim's employer). One subject was gang raped by 3 men; the rest were each sexually assaulted by 1 man.

Three of the victims had a heterosexual lifestyle; 1 was bisexually oriented; 1 was homosexually oriented; and 1 had not been sexually active before his victimization but subsequently adopted a homosexual lifestyle.

CLINICAL OBSERVATIONS

Combined data on 22 cases of male rape retrieved from both the offender and victim samples were analyzed in regard to six major factors: access to the victim, style of attack, type of sex acts committed, motivational components of the assault, history of sexual assault, and impact on the victim.

Access to the Victim

Men are assaulted where they live, work, travel, and relax. They appear to be at greater risk when engaged in solitary activities, such as hitchhiking. In 8 of the cases (36%) the victim was hitchhiking and the offender gained access to him by offering him a ride. In 1 additional case the victim was a passenger in the offender's car. In 8 cases (36%) the victim was engaged in an out-of-doors activity, such as swimming at a beach or hiking in the woods, when the offender approached him, and in 2 instances the victims were walking along the street, headed for a specific destination. Two other victims were in the offender's home, and 1 victim was a customer in the bar where his offender worked.

Style of Attack

The offender gained sexual control of his victim through three major methods: entrapment, intimidation, and/or physical force. In 3 cases the offenders entrapped their victims by first getting them drunk and then taking advantage of the victim's intoxicated state to sexually assault him.

> One victim, Mr. A, was at an office party and had too much to drink. His boss offered to drive him home and passed out in the car. A short time later he awoke to find himself naked on the backseat being sodomized by his boss.

A more common style of attack, however, was through some type of intimidation. In 12 cases the offenders intimidated their victims into submission by threats of physical harm and/or by brandishing a weapon.

> Mr. B was hitchhiking and was offered a ride by four men. He got into the back seat of the car, and as they drove off one of the men put a knife to Todd's throat and forced him to perform fellatio.

An equally frequent approach was an unanticipated attack in which the offender approached the victim by suddenly striking or physically overpowering him.

> Mr. C was sleeping in his barracks when he was awakened by a man who punched him in the chest and stomach and choked him. He then held Mr. C's face down on the bed and sodomized him.

Type of Sex Acts

In little more than half of the cases (N=12; 55%) only a single type of sexual activity occurred during the offense, and in a little less than half of the cases (N=10; 45%) several types of sexual acts (oral, anal, and masturbatory) took place. In the majority of the assaults (N=14; 64%) the offender sexually penetrated his victim in some fashion, whereas the offender accepted penetration (that is, he performed fellatio on his victim) in only 7 of the cases (32%). The most common type of sexual act was sodomy; in 10 of the assaults the offender performed anal intercourse on his victim. Oral penetration was the next most frequent act; in 8 of the cases (36%) the victim was forced to perform fellatio on his assailant. In 2 of the cases the offender made one victim perform sexual acts on another victim. One case consisted of the victim masturbating the offender, and in another case the offender used a foreign object to anally penetrate the victim.

What seems especially significant is that in half of the cases the offender made an effort to get his victim to ejaculate. Two offenders masturbated their victims, 7 performed fellatio on their victims, and 2 forced co-victims to fellate each other to the point of ejaculation.

Motivational Components

The motivational intent of the offender was analyzed through the accounts and details of the offense. Five major psychological components were prominent.

1. *Conquest and control.* All assaults served as an expression of power and mastery on the part of the offender.

> Afterwards he had tears in his eyes and said something like, "I hope you're satisfied," or, "I hope you got what you wanted," and I felt kind of funny because he was so upset. What was really exciting, though, was that all during the assault I felt in total control of him.

2. *Revenge and retaliation.* In some cases of male rape, the offense is activated by the assailant's anger toward his victim and is regarded by him as a form of retaliation.

> I cornered him in the showers and said, "You think I'm a punk? I'm going to prove you are what you called me." He was real scared and said, "Forget about what I said," and then he asked me if I wanted a hand-job. I said, "What do you think I am, a homo?" Then I told him, "You're going to give me some ass," and I fucked him. It wasn't for sex. I was mad and I wanted to prove who I was and what he was.

3. *Sadism and degradation.* For some assailants, aggression itself becomes eroticized, and they find excitement and gratification in the sexual abuse and degradation of their victim.

> I had the guy so frightened I could have made him do anything I wanted. I didn't have an erection. I wasn't really interested in sex. I felt powerful, and hurting him excited me. Making him suck me was more to degrade him than for my physical satisfaction.

Sexual sadism may be evidenced by bondage, ritualistic torture, and coprophilic acts. In extreme cases it may lead to lust murder, but for a variety of reasons such male homicides may not be identified as sex-related.

4. *Conflict and counteraction.* Another component in some male rapes is the assailant's attempt to punish the victim as a way of dealing with his unresolved and conflictual sexual interests.

> Mr. D, aged 20, drove around a city block where male hustlers cruised and picked out a man about his own age. They drove to a roadside rest area and parked. "After I came, I dragged him out of the car and punched him out and called him a punk. I told him I was going to kill him. Then I threw his clothes out of the car and took off. I was angry at him. I don't know why. At what I was doing, I guess, is what I was really angry at."

Such offenders seem caught in a bind: unable, on one hand, to admit their interests in sexual encounters with other males and unable, on the other hand, to abandon pursuing such encounters. They do not feel comfortable or secure with themselves in regard to their sexual identity or orientation. In some cases they project their feelings onto the victim and see him as a temptation. Then they become angry and attempt to punish him for arousing such interests or feelings in them.

5. *Status and affiliation.* Some offenders feel pressured to participate in gang rape to maintain status and membership with their peers. In addition to other motives, acceptance and recognition by one's peers becomes a dynamic in group rape, and mutual participation in the assault serves to strengthen and confirm the social bond among the assailants.

History of Sexual Assault

The current offense constituted the first conviction for a sexual assault for only 4 of the 16 offenders. (No dependable data were available in regard to the assailants of the victims interviewed). Of the 12 offenders who had a prior criminal record of sexual offenses, 6 (38%) had previously committed sexual assaults against other males; 4 had committed sexual assaults against females and 2 had sexually assaulted both males and females. Seven of the subjects with prior offenses had sexually assaulted age-mates, 4 adult subjects had assaulted adolescents, and 1 adult subject had assaulted a child. Apart from their sexual offenses, 9 of the offenders (56%) had no criminal record; 7 (44%) had a serious criminal history in addition to their sexual offenses.

Impact on the Victim

Male victims make it clear that 1) rape is stressful, 2) reporting the assault is difficult, and 3) one's lifestyle becomes disrupted.

That rape is often life-threatening to male victims is validated through the terminology used to describe the rape ("I was terrified . . . thought he was going to do me in"). Victims experience a wide range of mixed emotions and disbelief ("I was flabbergasted and didn't know what to do"; "I wanted to kill the guy but in the same token was afraid").

The male victims felt pressured into not reporting the rape for several reasons: 1) societal beliefs that a man is expected to be able to defend himself against sexual assault ("I don't think a lot of people believe it could happen . . . I'm 6'2" and weigh 220 pounds"), 2) the victim's sexuality may become suspect ("The police asked me a lot of wild questions . . . reporting puts your masculinity in jeopardy"), and 3) telling is distressing ("It's embarrassing to tell someone you've been raped").

The disruption in male victims' lifestyle could be seen in terms of physical reactions ("I couldn't eat or sleep for a while"), psychological reactions ("I think a lot about it by myself"; "I had a fear of men for quite a

while"), social reactions ("My friends kept asking what happened and I just felt they didn't believe me and I just got away from having friends"; "Didn't tell my family. They are conservative and who knows what they would think"), and sexual changes ("My sexual activity . . . ended").

Although male victims made concerted efforts to resume their usual lifestyle as quickly as possible ("I tried to get all organized . . . get to class . . . get everything done so I don't get totally behind"), on long-term follow-up they reported unresolved issues when the rape was not adequately addressed as a trauma at the time it occurred.

> Even a couple of years after, whenever I'd feel depressed or tired or something, this whole incident would come back to me. I'd think . . . what could I have done to prevent it?

Male victims also seemed to evidence considerable anger at having been raped and fantasized or planned retaliation against their assailants.

> I kept trying to figure out how I could get back at him. I thought of getting a gun and going out to revenge myself.

In those cases in which the offender attempted or succeeded in getting his victim to ejaculate, the victim was especially confused and concerned about this aspect of the assault.

> I always thought a guy couldn't get hard if he was scared, and when this guy took me off it really messed up my mind. I thought maybe something was wrong with me. I didn't know what it meant and this really bothered me.

DISCUSSION

Since rape is commonly misconstrued to be a sexually motivated crime, it is generally assumed that males are unlikely targets of such victimization, and that when it does occur, it reflects a homosexual orientation on the part of the offender. However, the cases of male rape that we have had an opportunity to study do not lend much support to either assumption. The gender of the victim did not appear to be of specific significance to half of the subjects. They appeared, instead, to be relatively indiscriminate with regard to choice of victim, that is, their victims included males and females, adults and children. This would tend to suggest an undifferentiated, or polysexual orientation. For the other half of these subjects, males appeared to be the specific targets of their sexual offenses. All of these offenders appeared to be sexually active with other males, but only 2 of them led predominantly homosexual lifestyles, in which the selection of a male victim would constitute a counterpart to the selection of a female victim by a heterosexual rapist. The other 4 offenders led bisexual lives but were conflicted about their sexual involvement with other males. The selection of a male as the target of their sexual assault can be seen in part as an expression of this unresolved aspect of their lives. The victim may symbolize what they want to control, punish, and/or destroy; something they want to conquer and defeat. The assault is an act of retaliation, an expression of power, and an assertion of their strength or manhood.

The selection of a male as a victim seemed even less significant than the choice of sex as the means of domination and retribution. Rape is a complex, multidetermined act prompted more by nonsexual than by sexual motives (2). There are several close parallels between cases of male rape and female rape. The age of the offender is quite similar in both types of rape, for example. Adolescence and young adulthood appear to be times of stress that activate the potential in some males who are prone to rape.

Although it is commonly believed that a male is powerful enough to defend himself from a sexual assault, he is in fact susceptible to the same techniques by which assailants gain control over their female victims. In many cases a combination of entrapment, intimidation, and brute strength were employed in the commission of the assault.

A major strategy used by some offenders in the assault of males is to get the victim to ejaculate. This effort may serve several purposes. In misidentifying ejaculation with orgasm, the victim may be bewildered by his physiological response to the offense and thus discouraged from reporting the assault for fear his sexuality may become suspect. Such a reaction may serve to impeach his credibility in trial testimony and discredit his allegation of nonconsent. To the offender, such a reaction may symbolize his ultimate and complete sexual control over his victim's body and confirm his fantasy that the victim really wanted and enjoyed the rape. This fantasy is also prominent in the rape of females (8).

As in the case of sexual assault of females, male rape (whether it occurs in the community or in an institutional setting) does not appear to be motivated primarily by the need for sexual gratification. Satisfaction and pleasure in male rape appear to be experienced in the sense of power, the discharge of anger, and the erotization of aggression more than in sexual release. Offenders equate manhood with being in control, being aggressive, and being the penetrator in sexual acts. Offenders differ in their need for control. Some offenders wish to control, others to control and to degrade, still others to control, degrade, and destroy. Sex becomes an instrument of control, retaliation, degradation, and punishment.

In conclusion, although we would not expect the incidence of male rape to approach that of female rape in our culture, we believe it is not so rare an event as would appear from reported incidents. We believe

existing stereotypes are responsible for males being reluctant to report rape, much as the attitude and atmosphere existed for female rape victims a decade ago. Thus, we believe it is important for clinicians to be especially alert to suspected sexual trauma in males of all ages and to be sensitive to such victimization when it is reported.

The average age for the victims referred and interviewed in this study was identical to that of the victims of the offenders interviewed. Both were 17½, an age that represents a transition from adolescence into adulthood. We suspect that as males become older they become increasingly reluctant to acknowledge sexual victimization. Although some states have revised their criminal codes in regard to rape to include male victims, other states have not, and such assaults do not constitute rape but are dealt with as sodomy offenses. According to most such statutes, both participants in an act of sodomy are guilty of "an unnatural act" or "a crime against nature," and although the victim may persuade others that the sexual encounter was forced rather than voluntary, such an admission may lead others and the victim to feel that his manhood has been tampered with. If the victim is gay, his sexual orientation may impeach his credibility in regard to his victimization. Although federal guidelines have precluded the introduction of the female victim's sexual reputation as a defense in rape cases, the sexual lifestyle of the male victim can still be used as a defense (9). As a result, then, of a combination of cultural, social, legal, and psychological issues, male rape remains one of the most unaddressed issues in our society today.

The Concept of Culture in Psychiatric Residency Education

BY EDWARD F. FOULKS, M.D., PH.D.

Diagnosis and treatment in psychiatry are heavily influenced by cultural factors. The author argues that the subject of culture warrants a place in the curriculum of psychiatric residency education. He outlines approaches to the teaching of cultural psychiatry that have been used successfully in several departments of psychiatry. He feels that although the medical model of understanding mental illness has demonstrated its effectiveness in chemotherapeutic, psychotherapeutic, and other treatments, the cultural model can often provide unique insights and approaches in patient care.

More than in other branches of medicine, diagnosis and treatment in psychiatry are never free from cultural factors. Clinical judgments, especially in psychotherapy, are never free from the influence of the therapist's cultural values. When the patient is from the same social class and ethnic group as the treating psychiatrist, therapy is often successful. Problems are encountered, however, when the psychiatrist attempts to use the standards of his or her background to evaluate and treat patients from a different background. Psychiatry, and especially psychotherapy, can never be completely free of such biases. At best, psychiatrists can attempt to develop sensitivity to and awareness of cultural differences between themselves and certain patients and in this respect to develop an appreciation of the patient's point of view. Insight into another's cultural background often provides therapeutic approaches that reduce the patient's misunderstandings and enhance a working doctor-patient relationship. Psychiatrists often obtain knowledge of and sensitivity to other cultures in their undergraduate education; sometimes these develop through personal experiences. In this paper I will argue that, in addition, the subject of culture warrants a place in the curriculum of psychiatric residency education.

Culture is an important factor in many aspects of psychiatric practice and theory; yet faculty who are involved in psychiatric education have struggled with designing courses in cultural psychiatry that would prove relevant to the clinical experiences of residents and students. In this paper I will outline approaches to the teaching of cultural psychiatry that have been used successfully in several departments of psychiatry. The purpose of presenting this outline is twofold: 1) to disseminate ideas regarding unique training approaches in cultural psychiatry and 2) to suggest an approach to the development of a sequential core curriculum in cultural psychiatry that would apply to all four years of psychiatric residency education.

Until recently, anthropology has been only peripherally related to the practice of psychiatry and has accordingly played a small but interesting, if not exotic, role in education programs for residents. Residents' seminars centering on, for example, speculations regarding the function of circumcision in primitive societies and its relation to the Oedipus complex have provided intellectual delight to many programs. With the advent of the community mental health movement, many psychiatry trainees faced problems of dealing clinically with patients whose cultural background was different from their own. In this situation the relevance of understanding cultural values, beliefs about the causes of and cures for illness, differences in status, working in an intercultural setting, and the role of the psychiatrist-physician in relation to other kinds of healers became major problems of clinical importance. Cultural psychiatry, however, is not limited or relevant only to residency education in community mental health centers serving ethnically diverse groups; it is fundamental in the training of general psychiatrists working in any setting.

Increasing efforts have been made recently in psychiatric residency education to develop an explicit curriculum. In this regard, the work of the American Association of Directors of Psychiatry Residency Training, the American Medical Association's Liaison Committee on Graduate Medical Education, and other agencies has resulted in increasing uniformity in the

Revised version of a paper presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12–18, 1979. Received June 6, 1979; revised Oct. 30, 1979; accepted Dec. 11, 1979.

From the Departments of Psychiatry and Anthropology, University of Pennsylvania, Philadelphia, Pa.

curriculum and clinical experience currently offered by residency education programs. I hope that the suggestions offered in this article will provide an impetus for developing a curriculum in cultural psychiatry as an integral part of basic residency training in psychiatry.

In 1978 the American Psychiatric Association created a Task Force on Cultural and Ethnic Issues in Psychiatry under the direction of Dr. John Spiegel. This group is charged with heightening the awareness of the importance of understanding the specific cultural, national, or ethnic backgrounds represented in our culturally diverse society. The task force is to emphasize the specifics of culturally differentiated diagnostic and treatment techniques for various ethnic groups. They are attempting to generalize and correlate a multi-ethnic and culturally appropriate mental health approach with other medical specialties. This group is also charged with conducting an inventory of the curricula of residency training programs with respect to the inclusion of the subject of cultural psychiatry and to develop model courses and bibliographies for use in psychiatric residency programs in the future.[1]

The need for training in this subject has long been recognized by residency accrediting agencies. The Liaison Committee on Graduate Medical Education has clearly recommended the inclusion of cultural psychiatry in residency education:

> The curriculum must include . . . sufficient material from the social and behavioral sciences, such as Psychology, Anthropology, Sociology, to help the resident understand the importance of economic, ethnic, social, and cultural factors in mental health and mental illness. . . . [Residents] must have experience in the care of patients . . . from a wide variety of ethnic, social, and economic backgrounds. . . . The residency program should provide its residents with instruction about American culture and sub-cultures. Many physicians may not be sufficiently familiar with the attitudes, values, and social norms prevalent among the various segments of contemporary American life; therefore, the curriculum should contain instructions about these issues adequate to enable the resident to render competent care to those patients from various cultural backgrounds for whom he has clinical responsibility in the course of his residency. (1, pp. 361–362)

In spite of these recommendations, many training centers have had difficulty developing a formal approach to the teaching of cultural psychiatry. This may represent difficulties inherent in the medical model of mental illness, which is sometimes interpreted as meaning that, for example, schizophrenia is schizophrenia and depression is depression, no matter what the patient's cultural background. There is, at times, an ethnocentric or at least a self-assured idea that an accurate diagnosis determines and prescribes an inevitable treatment process. Clinical experience often demonstrates, however, that the way individuals experience, identify, interpret, and communicate psychic function is determined to a very large extent by their culture. Furthermore, when, how, and from whom they seek relief, what treatments they understand and accept, and how long and to what extent they will comply are further functions of their background and culture. The value of an accurate scientific diagnosis is diluted when a patient does not show up for a follow-up appointment or cannot take blue pills for a "cold" illness or feels that the malady is caused by being out of grace with God.

Psychiatry training programs need to devote more attention to formalizing cultural factors in patient care and management. An increasing awareness of the pluralistic nature of our society has brought many of these issues to the fore. In addition, the advent of the community psychiatry movement, with its increased awareness of minority group issues, has brought a special focus on the practical relevance of the concept of culture in providing health and mental health services to these populations.

Culture plays a major role in shaping how people think, behave, and feel. Culture determines how and by whom children are raised, how they are cuddled and fed, how they acquire rules of behavior, how they are punished, and how they learn about sex, gender roles, and marriage. Culture may affect personal psychology and shape character. Culture provides standards and values according to which one evaluates the self, one's group, and outsiders. Culture provides guidelines and rules for recognizing or diagnosing emotional illness and for its management and, sometimes, treatment. When psychiatrists raised in one culture encounter people raised in another, some conflict and misunderstanding may result regarding many issues, such as how children should be raised, rules of behavior, gender roles, marriage patterns, standards and values for evaluating self and others, and how mental illness is perceived and dealt with (2).

CURRICULUM APPROACHES

Cultural Sensitivity Groups

Sensitivity and insight into one's own attitudes, reactions, and biases toward others have always been important aspects of residency training. Many residents seek or are directed to their own therapy or personal psychoanalysis to gain a better understanding of themselves and to increase their degree of objective empathy with their patients. In a paper presented at a conference at Boston University in April 1979, Charles and Elaine Pinderhughes proposed the usefulness of cultural sensitization and introspection in psychiatric residency training through the use of special short-term sensitivity groups in which each member is given

[1]John P. Spiegel, M.D.: Personal communication, Feb. 20, 1979.

the opportunity to talk about and explore his or her own ethnic background and assumptions as well as the stereotypes attributed to other ethnic groups. Actively exploring one's own cultural heritage with its unique values often brings to the fore many attitudes toward members of other ethnic groups that had been implicit in thought and action but out of the resident's awareness. The group experience is designed to render residents more sensitive and appreciative of differences between their own culture and that of their patients and others. As is usually the case with sensitivity groups of any kind, the group leader should be from outside the institution. Groups could be formed as a special retreat or for a short time and could use a visiting consultant whose purpose would be to create awareness of class and cultural stereotyping.

Didactic Courses and Their Content

Favazza and Oman (3) outlined major works in cultural psychiatry that relate the concept of culture to the practice of psychiatry and psychiatric theory. The scope of these studies includes 1) cross-cultural comparisons, 2) emics versus etics (culturally defined within-group definitions versus categories imposed by Western science), 3) subjective culture, 4) culture and personality, 5) culture, mental health, and mental illness, 6) the culture of mental hospitals, and 7) folk beliefs and rituals, which include folk classifications and etiology of mental illnesses, folk diagnosis, folk treatments, and folk healers, and 8) psychiatric epidemiology.

In an effort to structure a course in cultural psychiatry, residency programs in Canada have developed a set of educational goals and objectives that includes the contributions of the sociocultural disciplines to psychiatry (4). The final objectives determined most relevant to residency education included the following:

1. To attain an understanding of some of the concepts of culture and the idea that cultures have arrived at a variety of greatly diverse solutions to the problems of survival and the achievement of satisfaction.
2. To learn the range and diversity of marital and family patterns across cultures and the ecological forces that may determine them.
3. To have an awareness of some of the research concepts related to the mental health aspects of culture change and migration.
4. To become familiar with some of the main concepts and terms used by sociology when considering psychiatric phenomena.
5. To attain an understanding of what social class means and how it may be related to psychiatric disorders, psychiatric treatment, and the attitudes of psychiatrists.
6. To become familiar with research findings concerning relationships between various ecological factors and differential rates and patterns of psychiatric disorders.
7. To attain an awareness of some of the findings of studies concerning the social systems of psychiatric wards and the implications of these findings for reform.
8. To have an awareness that all cultures generate psychiatric disorders but that their forms may vary from culture to culture in a way that is linked to cultural symbols, belief systems, or modal personalities.
9. To learn that the prevalence, age of onset, duration, and outcome of psychiatric disorders may vary across cultures and that variations are often best explained in cultural terms.

This outline, with accompanying enabling objectives, provides the initial framework for a basic science course in cultural psychiatry for residents. Such a course would obviously be more theoretical than clinical but would have application and relevance to the field of psychiatry. Further topics that might be developed in a basic science didactic course include medical anthropology (5), basic theoretical approaches to understanding disease and illness (6), social integration and disintegration in relation to psychiatric symptoms (7), sociocultural change, modernization, and psychiatric disorder (8), poverty and psychiatric disorder (9), stress, coping, and adaptation in relation to class and ethnicity (10), alternative healing systems (11), and cross-cultural issues in psychiatric assessment and treatment (12, 13). A focus of the course should be on comparative studies of traditional healing and its relationship to psychotherapy, indigenous drugs and the use of special states of consciousness, and cross-cultural epidemiological studies of mental illness. Cultural influences on cognition, affects, and coping processes should be studied as they influence culture-bound syndromes and manifestations of psychosis, depression, and dissociative states. Videotapes and movies of healing rituals, trance states, and shamans' performances such as those developed by Simons[2] might prove useful in this regard.

The Society for Medical Anthropology has recently published a curriculum guide of undergraduate, graduate, and medical school courses in medical anthropology (14). Training programs, in liaison with colleges or universities, could provide opportunities for residents to take courses in sociology and anthropology. Interested residents might pursue formal graduate work toward a master's degree or doctorate when this could be conveniently integrated with clinical rotations.

Field Experiences

Residents learn material best when it is closely related to clinical experience. Therefore, it would be ideal if a didactic course in cultural psychiatry were accompanied or followed by an opportunity to apply the knowledge to a clinical setting. In a paper present-

[2]Ronald P. Simons: "Floating in the Air, Followed by the Wind" (16 mm. sound-color film). Gunter Pfaff, filmmaker. Indiana University Audiovisual Services, 1974.

ed at Boston University School of Medicine in April 1978, Alexander Leighton proposed guidelines for developing clinical applications of cultural psychiatry. Such experiences are intended to provide the resident with an understanding of culture and cultural processes. Leighton's recommendations were to develop a curriculum in cultural psychiatry that would foster, among other things, learning to interview with a reluctance to make assumptions based on one's own values without collaboration from the patient and learning to be sensitive in the interview to one's own cultural assumptions that might inhibit, embarrass, or intimidate the patient.

Curriculum development should proceed first by identifying an ethnic group often encountered in a clinic situation and then reading scientific literature relevant to that group. Residents should spend time acquiring the language or idiom of that group with some fluency, or at least learning about the language. They should enter relationships and friendships with people representing the culture (for example, they could arrange to live with or visit families from the culture). Residents might also be assigned to obtain from selected members of the cultural group the story of their lives; ideally, both men and women and young and old individuals should be interviewed. Some programs have provided opportunities for interested residents to spend time working within another culture in a foreign or rural area.

Study Groups

In Philadelphia we have extended seminars throughout the entire four years of residency training by offering an elective weekly study group in cultural psychiatry. The group is composed of Anglo and Hispanic residents, staff psychiatrists, psychologists, social workers, and other therapists who work in clinical settings that serve a predominantly Puerto Rican population. Special topics related to clinical care, such as family structure, the role of women, eating behavior, management of acute excitement, and problems of intercultural psychotherapy, are subjects for ongoing discussion, study, and research.

Clinical Experiences

If cultural psychiatry is to attain a high level of educational importance to residents, it should be directly linked to the problems they encounter in the actual diagnosis, treatment, and management of psychiatric patients. Psychiatric residents should treat some patients from cultural backgrounds other than their own. Special problems in the treatment of these patients are often encountered. Initially, the psychiatric resident might profit from supervised experiences in interviewing mentally ill patients from cultures other than his or her own. Supervision of interviewing should focus on developing a style that is as free as possible from implications or subtle slips reflecting cultural biases or ethnic or racial stereotyping. Cultural differences between clinician and client often generate many misunderstandings in both parties. True understanding of one another is made difficult not only by possible language barriers but also by the use of different body postures and expressions, the holding of different value systems, and the different modes used to communicate distress and affect.

The Anglo clinician might consider obesity in a Puerto Rican woman as a sign of emotional problems, but if the woman is married she might feel a certain pride and strength in her weight because it means she is a complete woman. What is considered an *ataque de nervios* in Puerto Rican culture, an expression of social (usually marital) turmoil, might be misinterpreted by an Anglo clinician and misdiagnosed as an acute schizophrenic episode. The fact that a native American patient does not reply to questions about how his mother or father might think or feel, which might be a manifestation of the patient's high regard and respect for his elders, might be interpreted by a non-native-American clinician as an inability to empathize with the feelings of his parents. The Western clinician treating the Asian-American patient might interpret complaints of belching in the absence of organic pathology as hypochondria. The patient, on the other hand, might be expressing the loss of *ch'i* ("life energy") and might more accurately be considered depressed. The American clinician treating a patient from a Middle Eastern background might also be impressed with the high degree of hypochondriasis, particularly complaints regarding the area of the heart, and not fully appreciate that the patient is directly communicating depression. The locus of affect in many people from Iran, for example, is in the heart and not in the mind.

The congruence of the patient's explanatory model of illness in relation to the clinician's explanatory model of illness often creates misunderstandings that interfere with adequate treatment. Patients who believe that the cause of their problems and illness lies outside of themselves and their control are often considered as lacking insight and not easily reached in psychotherapy. Implicit in this situation is a real difference between the patient's model of illness and the physician's model of illness. One maintains that the locus of causation is in the social situation or in the environment, the other that the locus of causation is within the psyche of the patient. The converse situation also occurs in psychiatric practice. Patients feel that the causes of their problems are in their childhood experiences or in their current manner of relating to others and do not want to be "drugged," but the physician recognizes symptoms of manic-depressive illness and prescribes lithium.

Noncongruence of explanatory models often leads to impasse in therapy and noncompliance and reinforces patients' stereotypes of clinicians and clinicians' stereotypes of patients. Many difficulties en-

countered in psychiatric treatment relate precisely to the differences between the scientific medical model of diagnosis and treatment of disease based on the realities of our modern empirical world versus other models of the world and human emotion and functioning that are often found in our patients. Many of these models are not fully translatable into the medical model. In fact, many are difficult for the physician to fully understand. At best, by explicating these models to their fullest, we should be able to appreciate the power of culture in determining what the patient feels is an illness, whom he calls on for help, and what modes the patient uses for treatment and in explaining why the patient will or will not comply with prescribed psychiatric treatments.

When folk models of medicine are at gross conceptual variance with standard psychiatric models, true understanding in the doctor-patient relationship will be precluded and treatment will be made more difficult. Cultural psychiatry provides possibilities for informed negotiation and for more efficient implementation of medical treatments in such populations. If the cognitive realities of the folk system are well understood, aspects of the folk system might actually be fruitfully used and incorporated into the delivery of adequate medical treatment. When discrepancies exist between the folk model and the medical model, programs might be instituted to better acquaint patients with the medical model—to attempt to transform their systems to correspond more with those with which we are more familiar.

Other Suggestions

A list of psychiatrists with expertise in treating patients from certain ethnic groups might be developed for purposes of special consultation or supervision. A more comprehensive consultant list might include clinicians from institutions other than the principal training program.

The works of Kleinman and associates (6, 15), Fabrega (16), Snow (17), and others in medical anthropology provide a theoretical framework for designing effective therapeutic approaches in cultural psychiatry. These approaches focus on the effect on diagnostic and therapeutic processes of patients' conceptions of their illness, the psychosocial problems associated with their illness experience, patient requests and expectations from specific clinical interactions, and negotiations aimed at establishing therapeutic goals. These approaches have been found particularly useful to residents doing hospital consultation-liaison with patients with nonpsychiatric illnesses.

Grand rounds might include detailed presentation of both psychiatric and sociocultural aspects of the patient's life situation. Formal discussants could include a sociologist and/or an anthropologist.

A journal club could discuss journals that focus on cultural psychiatry. Important journals in this field currently include *Transcultural Psychiatry Research Review, Culture, Medicine and Psychiatry, Social Science and Medicine,* the *Journal of Operational Psychiatry,* the *International Journal of Social Psychiatry, Ethos,* the *Journal of Cross Cultural Psychology,* the *Journal of Nervous and Mental Diseases,* the *Journal of Psychological Anthropology,* and the *Psychoanalytic Study of Society.*

MODELS OF MENTAL ILLNESS

Three models of understanding mental illness—the medical, the cultural, and the ethnopsychiatric—are fundamental to a curriculum in cultural psychiatry. I recently discussed these models in another paper (18). The medical model assumes basic biological and cognitive universals and uses the diagnostic categories familiar to psychiatry, the cultural approach centers on the various manifestations of psychiatric disorders in different societies, and the ethnopsychiatric approach attempts to discover the folk classifications that are based on the particular realities and world view of a certain cultural group. The clinical value and information derived from each of these approaches is often quite different. However, from a clinical perspective each may provide unique approaches to the alleviation of a patient's symptoms.

The medical model has demonstrated effectiveness in chemotherapeutic, psychotherapeutic, and other treatments of mental disease. The cultural model provides recognition of basic psychiatric disorders occurring in the context of culture and manifested in unique and culturally stereotyped ways. The ethnopsychiatric model provides an approach that is concerned with defining what is wrong from the patient's point of view and giving these concerns an important position in developing a treatment plan. This model also provides for consultation and liaison with healers and others from the patient's community in delivering treatment and follow-up care.

EDITORIAL

Beyond the Superego

What small child has not said to his parents, "It's not fair"? Parents themselves can be heard to remonstrate with their young children, "Now, be fair!" or, on the other hand, "Life isn't fair!" Both children and parents seem to know what each other means by "fair"—each tacitly agreeing to the concept of equitable treatment. Boszormenyi-Nagy and Spark have described in *Invisible Loyalties* (1) how parents act on the basis of their notions of fairness, which derive from their own experiences of just and unjust treatment. These legacies of transgenerational justice are passed on wittingly or unwittingly—perhaps leading to unfair or unrealizable claims on their offspring.

In "Trust-Based Therapy: A Contextual Approach," which appears in this issue of the *Journal,* Boszormenyi-Nagy and Krasner assert that intrafamilial trust is the basis of mental health and the foundation of psychotherapy, a radical shift in our current thinking. Their implied assertion that an important aspect of human relating is an intuitive sense of justice is akin to John Rawl's definition of "justice as fairness" as a basis of the social contract. This article—a summation of work with families over many years—integrates the insights of psychoanalysis and the concepts of systems theory as applied to families but proposes a more inclusive scheme based on intrafamilial ethics.

The ethical dimension that Boszormenyi-Nagy and Krasner emphasize is neither the superego of the Freudian model nor the traditional morality of religion. The authors refer to this dimension as "merited trust"; it refers to the long-term balance of fairness between the generations and within couples and derives from the existential fact that human beings are born into some form of the family and, inevitably, must come to terms with what they deserve, can expect to receive, and what is expected of them within that institution.

People act in ways they expect will gain them reciprocal behavior in return, and when they are treated in ways that they feel their past behavior has not merited, they feel treated unjustly. The bond of trust has been broken and the consequences are often mental "ill health." Parents expect to be and feel accountable to both their children and society for their treatment of them and in turn expect a certain loyalty from their children. Children do feel and act "loyal" to their parents—whatever forms this loyalty assumes. Uniquely among psychiatrists, Boszormenyi-Nagy and his collaborators have observed, investigated, and "treated" the twisted and fractured bonds of trust within families. We agree that a sense of justice is a dimension of human affairs which transcends individual psychology and is the relational matrix within which people seek and find value in their lives.

Researchers such as Bowlby have given us ample documention that "attachment" is a fact of human existence. Students of object relations have provided clinical data and explanatory theories to this effect, perhaps best expressed by an abused child patient of Fairbairn's who said, when asked if she wanted a "new, kind mummy," "No, I want my own mummy" (2). It is a human characteristic that we do have and need relationships and that each of us judges the ethical quality of these relationships.

The work of therapy is a "pragmatic strategy." It consists of identifying the remaining resources of trustworthiness in troubled families and disentangling the "invisible loyalties" that have perhaps come to be expressed in distorted ways.

However, that parents are "accountable" to their children and that children are "loyal" to their parents is accepted as a basic premise, whatever way these loyalties are expressed.

Just as parents are accountable to their children, therapists are accountable to their patients and to the significant others who will be affected by changes in one individual. Therapists cannot be neutral but must rather be partial in a "multidirectional way"—hearing each family member's claims on his or her own terms. Primary relationships and loyalties continue even if actual relationships with parents and grandparents have been severed. They are based on "roots in common." These are not substitutable by any other relationship and "contribute to an individual's uniqueness." Second, common bonds constitute an "ethical claim" requiring that relationships remain in fair balance and that trust be merited and maintained. Therapists have the opportunity to help a family to restore its uniqueness and integrity.

What is important about this article is that it makes us sit up straight and reexamine certain assumptions as we go about our work. It asserts that human beings *are* "entitled" to and do deserve a modicum of fairness, that "mutual trust" based on consideration and caring accumulates "merits," and that "merits" accumulated deserve to be recognized and repaid over the long term. This does not imply that life will always be "fair" in the short run or that people are "entitled" to all that they might wish. It does, however, maintain that long-term bonds of familial trustworthiness help people through periods of unfairness. It denies "the trap of the contemporary observer of human relationships: in this view repayment of obligations emanating from procreation is optional and depends on the participants' feelings and a variety of power manipulations."

Some questions come to mind: How does love enter the picture? What of giving that is motivated by the wish to give pleasure to someone one loves? Perhaps the authors are implicitly suggesting that the unconditional love between parent and child or in marriage exists as an aspect of roots in common while "merited" trust is a broadened conception of the semiconditional love of adult life. The complexities of how these dimensions of trust and love are worked out in human families need further elaboration.

In conclusion, however, we feel that this approach to helping people should enrich the work of all therapists, whether they choose to see individuals or families, and, we hope, further the already visible movement toward integration and an end to sectarian squabbles. It behooves all therapists to consider seriously their patients' "loyalties": it suggests that even in work with individuals the enduring value of the individual's family and social context must be appreciated or therapy may be merely temporarily palliative or even destructive. The overriding implication is that civilization and decency in human conduct need not be a repressive force but can be, and often is, a liberating source of mental health and creativity.

BRIEF COMMUNICATIONS

Effect of Anticonvulsants on Plasma Haloperidol and Thioridazine Levels

BY MARKKU LINNOILA, M.D., PH.D., MATTI VIUKARI, M.D., KYOSTI VAISANEN, M.D., AND JUHANI AUVINEN, M.SC.

Patients who had therapeutic plasma levels of phenobarbital and/or diphenylhydantoin had significantly lower plasma levels of haloperidol and mesoridazine, the active metabolite of thioridazine, than patients who did not receive anticonvulsants. Plasma thioridazine levels per se were not affected by concomitant anticonvulsant treatment. Biperiden, an antimuscarinic, antiparkinsonian agent, did not affect the plasma levels of these three neuroleptics.

Phenobarbital and diphenylhydantoin are well-known inducers of the cytochrome P_{450} enzyme system of the liver (1), which is responsible for the biotransformation of many drugs and hormones (2). The significance of the induction of this enzyme system for the metabolism of most psychotropic drugs has not been studied in man.

Neuroleptic drugs are initially transformed mainly by the cytochrome P_{450} system in the liver (e.g., haloperidol) or both P_{450} in the liver and the intestinal sulfoxidase, a different species of cytochrome P_{450} (e.g., chlorpromazine and thioridazine) (3, 4). Therefore, the rate of metabolism and the plasma levels of different neuroleptics may be differentially affected by the induction of the cytochrome P_{450} system of the liver. Since the steady-state plasma levels of neuroleptics are probably related to the antipsychotic potency of these drugs (5), knowing the effects of enzyme induction on the plasma levels of neuroleptics in man is clinically important.

In the present study we investigated the effects of concomitant treatment with phenobarbital and/or diphenylhydantoin on the steady-state plasma levels of haloperidol, thioridazine, and thioridazine's active metabolite, mesoridazine (6).

METHOD

The subjects were 30 mentally retarded patients (21 men and 9 women) from Vaalijala Hospital (range of WAIS IQs, 50–70) who suffered from agitation or aggressive outbursts that were severe enough to be treated with high doses of neuroleptics. Nine patients (7 men and 2 women; mean age, 23.3±4.4 years) who had a grand mal seizure disorder required anticonvulsant medication; 2 received phenobarbital, 3 received diphenylhydantoin, and 4 received a combination of these drugs. All the other patients (7 women and 14 men; mean age, 26.8±7.4 years) required no anticonvulsant medication. All patients had been in Vaalijala Hospital for a minimum of 3 months and received a regular hospital diet. No medication other than the anticonvulsants, the neuroleptics, and an antimuscarinic, antiparkinsonian drug were used during the study. Patients consented to participate in the study, which was accepted by the committee of clinical investigations at Vaalijala Hospital.

The experiment was designed as a double-blind crossover, with 2-week washout periods between the treatments with psychotropics, which were administered in a random order. The duration of the treat-

ments was 6 weeks each. The dose was increased to the maintenance level during the first week.

We investigated haloperidol, 10 mg t.i.d., thioridazine, 200 mg t.i.d., and placebo, all of which were administered in tablets with similar dissolution rates and identical appearance and taste. Biperiden, 2 mg t.i.d., was added to the regimen of 11 patients (mean age, 25.7±8.3 years, mean weight, 61.6±14.1 kg) at the discretion of the clinical investigator when patients exhibited extrapyramidal symptoms; 19 patients (mean age, 25.5±7.6 years; mean weight, 54.5±10.8 kg) were not given biperiden.

Blood samples (5 ml) for the measurement of the anticonvulsants and neuroleptics were drawn from an antecubital vein at 8 a.m. on the 14th, 28th, and 42nd mornings, 11 hours after the previous drug dose.

Plasma levels of anticonvulsants were quantitated by use of a routine gas chromatographic procedure (7). Haloperidol was measured with gas chromatography (8). Thioridazine was quantitated fluorometrically (9), and the level of mesoridazine was calculated by subtracting the thioridazine level from a fluorometrically measured combined level of thio- and mesoridazine (10). Significance levels were determined by analysis of variance.

RESULTS

The mean (±SD) anticonvulsant plasma levels of the 9 patients requiring such medication were within the established therapeutic ranges for diphenylhydantoin (12.0±5.1 g/ml) and phenobarbital (16.4±4.1 g/ml). They were not affected by the concomitant administration of haloperidol or thioridazine.

On the contrary, mean (±SD) haloperidol levels on the 14th, 28th, and 42nd mornings were 5.9±6.4, 6.6±3.2, and 19.4±5.7, respectively, in the patients receiving anticonvulsants and 9.9±6.8, 23.2±9.8, and 36.6±16.5 ng/ml in the patients not on anticonvulsants. The patients receiving anticonvulsants had significantly lower plasma haloperidol levels on day 14 ($p<.05$) and on days 28 and 42 ($p<.001$).

Plasma thioridazine levels were not significantly different between the two groups. The patients taking anticonvulsants had mean plasma thioridazine levels of 210±130, 430±220, and 580±280 ng/ml on days 14, 28, and 42, respectively, and in the patients not taking anticonvulsants they were 360±230, 520±210, and 650±260 ng/ml.

Mean plasma mesoridazine levels in the patients taking anticonvulsants were 1250±580, 2170±1070, and 2310±1070 ng/ml on days 14, 28, and 42, respectively, and in the patients not taking anticonvulsants they were 2230±1200, 2870±1110, and 3080±1100 ng/ml. The patients taking anticonvulsants had significantly lower plasma mesoridazine levels on days 28 and 42 ($p<.05$).

Biperiden did not affect plasma levels of the neuroleptics. Mean plasma haloperidol levels in the patients taking biperiden were 9.22±5.67, 16.50±12.33, and 27.82±20.23 ng/ml on days 14, 28, and 42, respectively, and in the patients not taking biperiden they were 8.38±7.50, 19.18±10.95, and 31.21±16.97 ng/ml. In patients taking biperiden mean thioridazine plasma levels were 350±100, 540±230, and 680±270 ng/ml on days 14, 28, and 42, respectively, compared with 290±230, 460±210, and 600±260 ng/ml in the patients who were not. Mean plasma mesoridazine levels on the 14th, 28th, and 42nd days were 910±760, 2510±1100, and 2600±1160 ng/ml, respectively, in the patients receiving biperiden and 1880±1380, 2630±1130, and 3060±1330 ng/ml in those not receiving biperiden.

DISCUSSION

We found that concomitant anticonvulsant medication significantly reduced the plasma levels of haloperidol ($p<.001$) and mesoridazine, the active antipsychotic, sulfoxide metabolite of thioridazine ($p<.05$) compared with an age- and sex-matched patient population with similar mental disorders and diets. Thioridazine levels did not differ significantly between the groups. Haloperidol doses need to be increased 200%–300% and mesoridazine doses 25%–40% (assuming linear kinetics) in patients on anticonvulsants to produce plasma levels comparable with patients not on anticonvulsants.

This pharmacokinetic report is part of an investigation to elucidate the necessity of chronic high dose neuroleptic medication to control agitation and aggression in an institutionalized mentally retarded patient population. The rationale for choosing haloperidol and thioridazine was to provide a comparison between a drug that was relatively free of autonomic nervous system side effects but had a significant potential to induce extrapyramidal symptoms and a drug that had the opposite pharmacologic profile.

The lack of an effect of anticonvulsants on plasma thioridazine levels may indicate that the sulfoxidation of this drug, which leads to the formation of mesoridazine, is the rate-limiting step of its biotransformation in man. The same step is probably rate-limiting also in the biotransformation of chlorpromazine (11). A given plasma level of mesoridazine is likely to have more neuroleptic activity than thioridazine because mesoridazine has a low degree of binding to plasma proteins (12). High levels of this metabolite are produced during oral therapy with thioridazine; therefore, it may be worthwhile to increase the dose of thioridazine in patients taking anticonvulsants who do not respond to a usual dose of the neuroleptic.

Earlier findings that trihexyphenidyl, lithium, and aluminum ion (13–17) lowered plasma chlorpromazine

levels could not be extended to the combinations of biperiden and haloperidol and biperiden and thioridazine in this study, perhaps because haloperidol is not sulfoxidated in the intestinal wall and thioridazine per se is a potent antimuscarinic agent (18). The antimuscarinic potency of thioridazine may be strong enough to abolish any effects of biperiden on gastric motility, the slowing of which by trihexyphenidyl, lithium, and aluminum has been suggested as the cause of the reduced bioavailability of chlorpromazine (13–17).

We conclude that anticonvulsants profoundly reduce plasma levels of neuroleptics whose biotransformation is primarily dependent on the cytochrome P_{450} enzyme system in the liver. To sustain therapeutic plasma neuroleptic levels, patients taking anticonvulsants may require doses of haloperidol that are 200%–300% higher than those required by patients not taking anticonvulsants; for patients taking mesoridazine and anticonvulsants, a 20%–40% dose increment of the neuroleptic may be required. The effect of anticonvulsants on haloperidol is similar to their effect on tricyclic antidepressants, which have been reported to induce low plasma levels in patients taking phenobarbital (19).

Psychiatric Problems in Third-Year Medical Students

BY MICHAEL H. SACKS, M.D., WILLIAM A. FROSCH, M.D., MARTIN KESSELMAN, M.D., AND LYNDA PARKER, M.D.

Each year as many as one out of four medical students experience sufficient emotional pain to seek psychiatric consultation. In many cases the precipitating stress relates to specific stresses associated with the phase of training. In the third year increased clinical responsibility may evoke feelings centered on caretaking, sexuality, and aggression that cannot be contained by an as yet fragile emerging professional identification. The authors present four case histories of third-year medical students to illustrate the complex interaction between family background, motivations to enter medicine, and the specific patient experience that resulted in sufficient distress to require psychiatric consultation.

As many as one-quarter of medical students seek a psychiatric consultation before graduation from medical school (1). Although students' reasons for seeing a psychiatrist differ, each year of medical school has distinctive patterns of stress (2). Characteristically, first-year students experience anxiety or depression in response to confronting a mass of information that cannot be learned in its entirety. This situation contrasts with the student's earlier undergraduate experience, in which specific guidelines were provided regarding the material to be mastered. Alternatively, the student finally in medical school may feel free for the first time to question his or her motivation for entering medicine. In the second year, the student's initial experiences with death and pathology often result in hypochondriacal fears and preoccupation. In the third year, patient contact often provokes a crisis related to issues of intimacy and closeness. Increased responsibility and anticipation of yet greater responsibility may produce sufficient emotional discomfort in fourth-year students to result in a psychiatric consultation.

Although this phase-related scheme is of some value, its application requires caution. The interaction between premorbid personality and the stresses of a particular year may not be simple. This scheme does, however, draw attention to the possible importance of school experiences to a student's request for psychiatric help (3).

In this paper we will describe four medical students who received treatment during their third year. Our purpose is to focus on the complex interactions between premorbid personality, life experience, and the particular stresses of the clinical year of medical school.

CASE REPORTS

Case 1. Mr. A, a 27-year-old man, sought treatment after receiving a low but passing mark in medicine that severely depressed him because it seemed unfair. He emphasized that the grade did not reflect his devotion to patients. In particular, he described intense involvement with a preadolescent female patient who had leukemia; he said that unlike other students he was spending an extraordinary amount of time with his patient, and at times could not study or complete written work because of a need to see how she was doing.

Initially treatment focused on Mr. A's belief that he was entitled to special treatment despite his not having accomplished the expected work. This expectation was related to his becoming the "man of the house" at age 10 when his father died. His wish to become a physician also appeared then, partially as a result of an identification with a well-known uncle. This feeling of entitlement was accompanied by intense guilt, which Mr. A began to appreciate when he realized that he frequently provoked people in authority to reprimand him.

After mentioning that he had once again unknowingly provoked an attending physician, Mr. A reported the following dream: "I have a bar in my head. It extends from temple to temple. It is removed by a plastic surgeon in the OB-GYN operating suite." Mr. A associated the bar in his head with the devil's horns and related the dream to his belief that he was an evil person with evil wishes. The psychiatrist suggested that perhaps the horns represented sexual wishes and that his need to punish himself for them might have been responsible for his having provoked the attending physician to rebuke him. Mr. A became silent and then said, "I guess I

might as well tell you." He reported an encounter with an 11-year-old girl whom he had befriended that had sexual overtones which disturbed him.

Mr. A justified his interest in the girl on the basis of his wish to become a specialist in adolescent medicine. In subsequent sessions it emerged that during his adolescence he had become overwhelmed by intense sexual feelings toward his younger sister. Reaction formation toward these feelings emerged as a central determinant in his decision to become a physician. Being closer to this goal during his medical clerkship intensified these latent sexual urges and the guilt attending them. This intensification resulted in his symptomatic preoccupation with caring for the young female patient, which resulted in his neglecting his academic work and seeking therapy.

Case 2. Ms. B, a 27-year-old engaged woman, had an intense anxiety reaction during her psychiatry clerkship. The precipitant was not clear. As treatment proceeded Ms. B spoke of her wish to be a "superwoman." By this she meant that she should be very successful as a wife and mother as well as a physician. The anxiety attack occurred while she was caring for a patient whose mother was a professional. She feared that her own professional strivings might result in her proving to be an inadequate mother. Her own mother had abandoned a promising career to devote herself to raising a family and Ms. B felt that a woman's primary responsibility was her family and that only men were entitled to a profession. This conflict over role also appeared in the severe crisis she had had in choosing her specialty. She wanted to be a cardiologist but felt that a woman should be a psychiatrist.

While on a medicine rotation, Ms. B was complimented on her work and encouraged to become a cardiologist. That afternoon while at rounds she felt isolated and had the following fantasy: "It was like they were players on a football team in a huddle drawing diagrams of the next play and I could never join the huddle." The therapist related this to previous feelings that she could not be successful at what she wanted because she was not a man. Ms. B recalled that she had always felt this way. As a preadolescent she would go horseback riding with friends and they would always play Indian boys because "Indian girls did not get to ride horses and did not have fun like Indian boys." She felt she could not become a cardiologist unless she became a man, which caused her anxiety in anticipating her future role as a wife and mother. She had long felt that she would have to become a psychiatrist or a pediatrician because those were the parts of medicine that were for the "squaws." It was now easier for Ms. B to examine her envy of men and the privileges and excitement that they seemed to have, as well as her feelings of inadequacy as a woman. The reasons behind her previous rejection of a career as a nurse became clear; it was a woman's profession and one primarily involved with caring. The only good professions were those that belonged to men. The anxiety attack during her psychiatry clerkship was determined by multiple conflicts over professional and sexual roles that were triggered by the specifics of a particular clinical relationship.

Case 3. Ms. C, a 24-year-old woman, entered treatment early in her third year because of the acute onset of anxiety and depression. Her mother had given up her career on the birth of her first child. Her father was marginally successful and had been forced to give up greater aspirations when Ms. C was an infant. Her mother felt she had "come down in the world" as a result of her husband's failure and therefore the sacrifice of her own career became particularly difficult to accept.

Ms. C's parents often argued. The arguments were generally initiated by the mother, and the father would withdraw from her anger with a tolerant and long-suffering air. Between these arguments the mother would appear depressed and resentful, sometimes withdrawing into her room for days. The "crazy" behavior of her mother frightened Ms. C profoundly, while the father's distant attitude aroused her contempt, a feeling she now frequently felt toward men.

During her childhood Ms. C played the role of the troublesome scapegoat, drawing her parent's blame and rage on herself. Inside she felt empty, bad, and ineffective. Away from her home for the first time, during college she reacted to these feelings by use of drugs and sexual behavior out of keeping with the conventional values held by her family. Her decision to go to medical school represented a dramatic change in this rebellious pattern. However, in medical school she joined organizations that sought to protest injustice in medical care for the poor. Although she found close women friends, partly through these political activities, her relations with men were sporadic, distrustful, and vaguely contemptuous. A victim-victimizer pattern characterized her intimate relationships and was accompanied by vacillations between intense anger at intimates and guilty depression.

In contrast to her competence in clinical situations, Ms. C appeared frightened, disorganized, and fragile in treatment. At other times she complained that her male therapist was critical, harsh, and cold. One session she arrived acutely and severely depressed. She had barely slept for three nights, which she had spent at the bedside of a young mother dying of a brain tumor. She was preoccupied by the thought of the dying woman's children, who would never really know their mother. Her feelings toward the patient were less painful, although complex; at times horror and pity that one could die so young, sometimes rage, at times survivor guilt (the patient and she were the same age). Her long bedside vigils, which were inappropriate, appeared to represent an attempt to rescue the child-patient with love where medication failed. For the next three days Ms. C's depression mounted, culminating in her taking a nonprescription sleep medication in what she recognized to be a suicidal gesture.

For this borderline woman, intellectual achievement and identification with various social ideologies had permitted a superficially adequate level of vocational and social function in spite of the disruptive rage she experienced in close interpersonal relationships. The choice of medicine as a career was a final ideological commitment, an altruistic defense against her own demandingness and rage. As long as she could cavil at the coldness and technological alienation of her fellow students and house officers, she could maintain her posture of being aloof and uniquely virtuous. However, the alternation of her identification with the abandoned children of the dying woman with guilt over her failure to assuage the mother's suffering appeared to evoke feelings previously dissociated from her professional life.

Case 4. Mr. D, a 24-year-old medical student, had a history of panic attacks and depression, which began during his OB-GYN clerkship. He had suicidal ideation, which seemed to be precipitated by a letter from his girlfriend ending their

four-year relationship. In treatment he later revealed that he had never had a sexual relationship with her and suspected that she was homosexual.

As a child, Mr. D's older sister was always considered sick and required psychiatric treatment. He remembered that she would throw temper tantrums which gained her parents' attention; he unsuccessfully attempted to gain their favor by being the "good child." When Mr. D was ready to attend college both his parents sought additional professional training. This left no money for Mr. D's education at the private college he had wished to attend. He accepted the situation without complaint and attended a local college. He could not recall why he decided to enter medicine, only that his family was not impressed when he was admitted to a medical school.

Mr. D described his mother as incredibly bitter and he resented her confiding to him about his father's sexual inadequacies and her suspicion that he was having an affair. Mr. D was also angry that his mother saw herself in her profession as a caring and nurturing woman, which he saw as incongruous with her harshness, bitterness, and castrating attitudes toward his father. He also had disturbing memories of how his mother punished his sister when they were young, and he thought these experiences were somehow responsible for their problems.

When Mr. D began his pediatric rotation, he found that he often became enraged at children's families. This would then trigger suicidal thoughts. He related this anger to his own family's neglect during his childhood and during his recent psychiatric difficulties, when they refused to be involved in his treatment.

Mr. D realized that the suicidal thoughts related to guilt regarding his "annihilating anger" and that his decision to be "good" as a child was not related to a passive acquiescence to his parents' wishes but rather to competition for the attention of his mother, first with the sister and later, during college, with his father. This anger at his mother may have been intensified during his OB-GYN rotation when he had to care for older women, but this hypothesis was never directly confirmed. The loss of his girlfriend at this time did, however, evoke similar feelings of rage, which Mr. D was unable to contain by being the "good little boy" or the good and caring doctor.

DISCUSSION

These four patients experienced anxiety during their third-year clerkship. The anxiety was occasioned by their work with patients whose situations resonated with the unconscious conflicts associated with becoming a physician. These conflicts were related to childhood conflicts over sexuality (patients 1 and 2), anger at maternal deprivation (patients 3 and 4), and sibling rivalry (patients 2 and 4). During the clerkship year they found it particularly difficult to contain their anxiety and had to seek psychiatric care. It is apparent that their decisions to enter medicine were partially determined by insufficiently sublimated conflicts.

The clerkship year may specifically stress those students whose motivation for entering medicine is to provide for others what they felt they did not themselves receive as children. Vaillant (4) found that physicians appear to be more vulnerable to psychiatric difficulty if they experienced their childhood as unhappy and deprived. If in caring for their patients these physicians were unable to obtain care for themselves they were particularly vulnerable. Closely related to this problem is channeling the intense anger at the depriving parents into behavior toward patients, families, teachers, or toward the self, as happened in the suicidal impulses of patients 3 and 4. Although issues of being cared for and mothering were important for all the patients, for patients 1 and 2 other issues were also involved.

In the case of patient 1 unresolved sexual problems were predominant. In the case of patient 2 guilt over her aggressive wishes to be able to compete and her envy of men were central.

In each case conflicts contributed to the career choice of medicine. Although one assumes that such conflicts often contribute to career choice, these four patients were unable to maintain the adaptive aspects of their attempted conflict resolution. During the preclinical years they had minimal difficulty; their ideas of the doctor-patient relation were still idealized, not yet subject to the intimate confrontation that actual care of patients requires.

The doctor-patient relationship for these students evoked feelings that centered predominantly on caretaking, sexuality, or aggression rather than on professional concerns. Many medical students struggle with such neurotic determinants of career choice and use a wide variety of adaptive maneuvers, both group and individual, to successfully master the conflicts that are stirred up by patient contact. Chronic detachment, the depersonalization of the patient to a diseased organ, overinvolvement with nonmedical aspects of the patient, and identification with a house officer are examples of common adaptive maneuvers. All of these four students were acutely aware of this usual process; they experienced part of their problem as a sense of isolation from their peers, of being unable to treat patients in the way their peers seemed to. By paying attention to the student's struggle with a fragile sublimation, the therapist who treats the third-year student can help him or her understand the fantasies and anxieties that working with patients produces.

When medicine is chosen to resolve insufficiently sublimated personal conflicts, specific clinical experiences may so resonate with intrapsychic problems that the adaptive aspects of the choice are lost and symptoms appear. While this may in part be phase-related, it is also particular to the individual student and life experience. While phase-related aspects of the clinical clerkship are perhaps most important for the treatment of the healthy student who experiences difficulty, it is critical not to overlook the importance of individual conflicts in students with more serious pathology. If these are not adequately dealt with in treatment, they

are likely to recur periodically during practice, too often to the detriment of patients, physician, and the profession.

Adult Psychiatric Disorders in Parents of Hyperactive Children

BY JAMES MORRISON, M.D.

The family histories of 140 children and adolescents with hyperactive child syndrome were compared with the family histories of 91 psychiatrically ill, age- and sex-matched patients who had a primary diagnosis other than hyperactive child syndrome. Parents of hyperactive children were more likely to have antisocial personality and Briquet's syndrome (hysteria) than were parents of nonhyperactive children; 11% of the hyperactive children had a parent with such a diagnosis. Parents of nonhyperactive children were more likely to have endogenous psychosis. The diagnosis of alcoholism did not significantly differentiate parents of the two groups of probands. These data support earlier studies and suggest a specific association between hyperactive child syndrome and the personality disorders of antisocial personality and hysteria.

In the early 1970s two studies (1, 2) were published on the family histories of children with hyperactive child syndrome. These studies found a high prevalence of antisocial personality and Briquet's syndrome (hysteria) among parents of hyperactive children, and this finding has provided the cornerstone for the argument that the hyperactive child syndrome is in some way related to personality disorders in adults. One objection to this conclusion is that no study has compared the family histories of hyperactive children with the family histories of nonhyperactive psychiatric patients. This study will report such data.

I compared the family histories of a group of hyperactive children with the family histories of a group of psychiatrically ill children seen in a private-practice setting. In essence, this study replicates the two earlier family investigations of hyperactive child syndrome and at the same time tests the findings of these two studies for specificity.

METHOD

Over a 6-year period, 391 children and adolescents were seen as part (30.1%) of a general private psychiatric practice. Patients and their parents or guardians were administered a structured interview, which covered symptoms, family histories, and demographic and social data (3). From these interviews I selected 140 case histories of children who manifested hyperactive child syndrome. These patients met the criteria of Stewart and associates (4), were not adopted, and had at least normal intelligence. Family history did not serve as a criterion for this diagnosis. For the nonhyperactive comparison group I selected 91 case histories of patients, who were generally diagnosed according to *DSM-II* criteria, were psychiatrically ill, nonadopted children, and were matched for sex and age (within 2 years). In both groups only 1 child was selected from each family.

Diagnosis of adult psychiatric disorders in the families of these patients was based on the criteria of Feighner and associates (5). In a few instances, particularly those involving divorced parents who were not

[b]Psychiatrically ill, but no specific diagnostic information available.

available for interview, the criteria had to be modified as suggested by Andreasen and associates (6). Whenever there was doubt about the diagnosis of a parent, the tendency was to err on the conservative side. This may have resulted in a number of undiagnosed psychotic and nonpsychotic illnesses, even among interviewed parents. Because of the great subjectivity and many meanings attached to hysteria, I made no diagnosis of Briquet's syndrome without full research criteria.

RESULTS

Of the 140 hyperactive children, 111 (79%) were boys; of the 91 nonhyperactive children 73 (80%) were boys. Mean ages were 11.8 years and 13.1 years, respectively. Ten percent of the children in each group were not white.

Definite and probable diagnoses of the nonhyperactive children were as follows: 31 (34%) had affective disorder, 11 (12%) had schizophrenia/schizophreniform psychosis, and 11 (12%) had situational adjustment reaction, 8 (9%) had personality disorder, 6 (7%) had organic brain syndrome, 6 (7%) had habit pattern disturbance, 5 (5%) had alcohol or drug abuse, 1 (1%) had school phobia, and 1 (1%) had anorexia nervosa. Eleven (12%) of these children were psychiatrically ill, but the type of illness could not be diagnosed.

Psychiatric diagnoses of the parents of both groups of children are given in table 1. Parents of hyperactive children were slightly more likely to have a psychiatric diagnosis and to have affective disorder. Schizophrenia and schizophreniform psychosis were more common ($\chi^2=7.63$, $p<.01$) in the nonhyperactive group. Somewhat more parents of hyperactive children were psychiatrically ill, but the specific illness was undiagnosed.

Antisocial personality and Briquet's syndrome were encountered far more often in the parents of the hyperactive group (χ^2 for the combined personality disorders=5.52, $p<.02$). Sixteen (11%) of the hyperactive children had at least one parent with Briquet's syndrome or antisocial personality; only two (2%) of the parents in the comparison group were so affected ($\chi^2=5.32$, $p<.05$).

To determine if the high prevalence of personality disorder in the parents of the hyperactive children could be correlated with previously undetected conduct disorder in the children, these children's records were reviewed again. Even applying *DSM-III* criteria retrospectively, no conduct disorder could be identified in these 16 children. In fact, on closer inspection these children looked like typical hyperactive children: their mean age, 9.9 years, was somewhat below the group mean, and 14 (88%) of them responded in typical fashion to psychostimulants or to tricyclic antidepressants, compared with 69% for the hyperactive group as a whole.

Alcoholism was found to exist slightly more often in the parents of the hyperactive group than in the parents of the nonhyperactive group ($\chi^2=1.84$, $p>.10$).

DISCUSSION

Dubey (7) has discussed several suggestions for investigators studying possible organic etiologies of the hyperactive child syndrome, including a comparison with deviant control groups to demonstrate specificity. In this study the family histories of a group of hyperactive children were compared with the family histories of psychiatrically ill children seen in a private practice setting. The problems of nonblind diagnosis remain, of course, although they are mitigated to some extent by insistence on adhering to strict diagnostic criteria whenever possible. This study replicates the two earlier investigations (1, 2) and tests their findings for specificity.

The most important finding of the previous studies was the high prevalence of antisocial personality and Briquet's syndrome among parents of children with

hyperactive child syndrome. This is the third study that concludes that personality disorders of antisocial personality and Briquet's syndrome are found in excess in parents of hyperactive children. The argument is thus strengthened for a specific relationship between hyperactive child syndrome and these two personality disorders.

The opposite conclusion must be drawn regarding alcoholism. The two earlier studies found a significant excess of alcoholism among the parents and extended families of hyperactive children, but the data reported here cast doubt on the importance of the previous findings. Although in this study alcoholism was nearly as prevalent among parents of hyperactive children as it was in the previous two studies, these figures only slightly exceed the incidence of alcoholism in parents of nonhyperactive children.

The near absence of schizophrenia and schizophreniform psychosis in parents of hyperactive children as compared with parents of nonhyperactive children supports my earlier speculation (8) that hyperactive child syndrome and endogenous psychoses may be negatively associated. However, as schizophrenia does occur in formerly hyperactive adults (9), the two conditions cannot be considered mutually exclusive.

A genetic mechanism has been proposed for the transmission of childhood hyperactivity from one generation to another; support for this hypothesis was reviewed by Cantwell (10) and earlier by Omenn (11). Although the data presented here cannot support a genetic etiology for this condition, they strengthen the view that the syndrome is a familial condition that is specifically related to the personality disorders of antisocial personality and Briquet's syndrome. Hyperactive child syndrome is probably unrelated to affective disorder and to schizophrenia. The specificity of a relationship between hyperactive child syndrome and alcoholism reported in earlier studies now appears questionable. Heightened awareness of a specific association between hyperactive child syndrome and the personality disorders described may provide the basis for further scrutiny of the symptomatology, pathophysiology, and treatment of this common childhood disorder.

A Comparison of Cognitive Impairment Due to Benzodiazepines and to Narcotics

BY NELSON HENDLER, M.D., M.S., CINDI CIMINI, M.S., TERENCE MA, AND DONLIN LONG, M.D., PH.D.

In an attempt to determine the source of cognitive impairment in 106 consecutively admitted patients at the Johns Hopkins Chronic Pain Treatment Center, EEG, the Wechsler Adult Intelligence Scale, Memory Quotient, and Bender Gestalt tests were administered. Patients receiving benzodiazepines alone demonstrated alterations in cognitive functioning and EEG evidence of a sedative effect. Patients receiving narcotics alone and a group of patients not receiving medication did not show signs of cognitive impairment. The effects of benzodiazepines on sleep and perception of chronic pain, in combination with the cortical changes that they produce, imply that these drugs should not be used in most patients with chronic pain.

The use of benzodiazepines has become widespread in the clinical practice of medicine, to the point that 97% of physicians in general practice prescribe drugs in this category (1). While benzodiazepines have been used to treat anxiety, insomnia, headaches, hypertension, and other psychophysiological problems, their efficacy in the treatment of chronic pain has, to our knowledge, never been demonstrated. Nonetheless, in a recent study conducted at the Johns Hopkins Hospital Chronic Pain Treatment Center,[1] 43% of the patients were found to be taking benzodiazepines by prescription from the referring physician. In fact, the use of benzodiazepines in patients with chronic pain would theoretically be ill-advised because they reduce the turnover of serotonin (2), thus interfering with natural sleep and lowering the tolerance to chronic pain (3, 4). However, the most significant problem that benzodiazepines create seems to be cognitive impairment with associated EEG changes, which mimic the patterns seen with other sedative and hypnotic drugs (5). Acute, single-dose administration of diazepam does seem to produce impairment in learning, memory, and psychomotor functioning (6).

While the long-term use of narcotic agents in patients with chronic pain is also contraindicated, approximately 80% of the patients admitted to the Chronic Pain Treatment Center of Johns Hopkins Hospital were also receiving these drugs (7). However, the evaluating psychiatrist noted that a great deal of cognitive impairment seemed to occur more often in patients using benzodiazepines than in patients using only narcotics. The following study was conducted in an attempt to verify this impression.

METHOD

Data were collected from 106 consecutively admitted patients at the Chronic Pain Treatment Center at Johns Hopkins Hospital. In an attempt to assess each patient's drug intake for the one month prior to admission, a history was obtained from the patient, the patient's family, the referring physician, and/or a qualitative drug screen for benzodiazepines, sedatives, hypnotics, and narcotics. Cognitive impairment was studied by administering both the verbal and performance scales of the Wechsler Adult Intelligence Scale (WAIS). If the difference between the two scale scores exceeded 12 points, it was considered abnormal. In addition, a Memory Quotient was obtained, and if the score was 15 points below the total WAIS score, it was considered abnormal. Finally, the Bender-Gestalt test was administered, and scores greater than 70 were considered indicative of psychomotor impairment.

EEG recordings were obtained from the laboratory at the hospital and were considered compatible with a sedative or benzodiazepine effect only if a great deal of 12–20 cps or 15–30 cps (beta) activity was reported by an objective observer, who was unaware of the patients' medication intake. EEGs with moderate or fair amounts of beta activity were considered normal. It is important to note that at no time were any of the EEGs

interpreted as having a pattern indicative of narcotic toxicity. Any patient having an EEG with an epileptogenic focus, or any indication of slowing compatible with arteriosclerotic cardiovascular disease or the effect of psychotropic medication, was eliminated from the study.

Patients below the age of 21 and above the age of 70 were not included in the study. The average age for the group of patients taking just narcotics was 43.4 years (range of 22–69), while the average age for patients taking just benzodiazepines was 41.8 years (range of 26–65). Patients with a history of alcoholism or barbiturate, hypnotic, or stimulant use were not included in the study.

RESULTS

Of the 106 patients, 64 (60%) were taking benzodiazepines. This represented the patients admitted during a 6-month period (February through July 1979). Only 6 patients were not taking any medication for 1 month prior to admission; 21 were taking narcotic agents alone; and 18 were taking benzodiazepines alone. Thirteen of the 18 patients taking benzodiazepines alone had an EEG, as well as the full battery of psychological tests (WAIS, Memory Quotient, and Bender-Gestalt); 13 of the 21 patients taking narcotics alone also completed the same battery of tests. Finally, 5 of the 6 patients not taking any medication were also able to complete the entire battery of tests. When these 31 patients were compared using a chi-square analysis (see table 1), there was a significant impairment in cognitive functioning among the persons taking benzodiazepines compared with the patients not taking drugs or narcotics. When this finding was further assessed, using the measures of cognitive functioning alone, regardless of the EEG outcome, it was found that 10 of the 13 patients taking benzodiazepines had signs of cognitive impairment, compared with 4 of the 13 patients taking narcotics alone (p<.02, chi-square analysis; see table 2). None of the 13 patients taking narcotics alone exhibited any EEG changes, while 8 of the 13 patients on benzodiazepines had 12–20 cps or 15–30 cps diffuse fast-wave activity present in a large amount. The difference between these groups of patients was significant (p<.001; see table 3). Finally, it was found that none of the patients taking narcotics demonstrated both EEG changes and impairment in cognitive functioning, compared with 7 of the 13 patients taking benzodiazepines (p<.002; see table 4).

It is significant that 40 of the 106 patients were taking both a benzodiazepine and narcotic at the time of admission. Of these 40 patients, 37 completed the battery of tests; when they were compared with the 13

patients taking narcotics without benzodiazepines or any other sedative drugs, a highly significant difference ($p<.001$) was found (see table 5).

DISCUSSION

The pronounced sedative effect produced by benzodiazepines on EEG activity is well-documented in the literature (8), but unless toxic proportions are reached, narcotics do not produce any measurable EEG effects (with the possible exception of alpha peak slowing) (5, 9, 10). In addition, when narcotics are given at the dosages commonly seen in clinical practice, they do not impair cognitive functioning, memory, or performance of visual and motor-perceptual tasks (5, 11). By comparing the two populations that were mutually exclusive, that is, the patients receiving benzodiazepines alone versus those receiving narcotics alone, one could conclusively state that benzodiazepines were far more likely to produce cognitive impairment, with concomitant EEG changes, than were narcotics. Finally, it is apparent that any cognitive impairment noted in the patient receiving both narcotics and benzodiazepines is far more likely to be due to benzodiazepines than to narcotics.

While neither narcotics nor benzodiazepines should be used on a long-term basis, cognitive impairment was far more apparent with the latter class of drugs. The question of the reversibility of the benzodiazepine effect is the subject of current research, but at this time one may only underscore a recent suggestion by the Food and Drug Administration (12) that benzodiazepines be limited to short-term use (i.e., 4 months).

Why Psychiatry Is a Low-Paid Medical Specialty

BY STEVEN S. SHARFSTEIN, M.D., M.P.A., AND HARRY W. CLARK, M.D., M.P.H.

The authors examine the effect of economic forces on the income of psychiatrists and compare the economic position of psychiatry with that of the rest of medicine. Since 1970 the income of psychiatrists has been losing ground compared with that of other medical specialists, although recent data suggest a possible improvement in the economic position of psychiatry. The authors believe that psychiatrists' incomes are important as a sign of the value of psychiatric care and as one measure of the economics of practice, that is, the incentives related to the distribution of scarce technology and labor in the service delivery system.

In May 1975 at the 128th annual meeting of the American Psychiatric Association, Dr. Bertram Brown, then Director of the National Institute of Mental Health, predicted, "Psychiatry will continue to grow in size and diversity" (1). In recent years, however, the number of American medical graduates selecting psychiatry has declined and the percent of all graduates has decreased. Since 1970 psychiatrists in private office practice have consistently earned less than other medical practitioners. This paper will examine the effect of economic forces on the income of psychiatrists and relate the economic position of psychiatry to that of the rest of medicine. There are some recent signs that the precarious situation of psychiatry is being improved through better coverage under health insurance, better peer review, and an enhanced status as a medical subspecialty.

THE ECONOMIC POSITION OF PSYCHIATRISTS

Since 1968 the American Medical Association has systematically collected data on the income of U.S. physicians. Since 1970 psychiatry has been losing ground compared with the rest of medicine. Table 1 shows the change within the years 1970–1976. It was during this time that psychiatry lost the most ground. The average net income of office-based psychiatrists increased less than 4% from 1970 to 1974, while the average net income for all U.S. physicians increased more than 20%. As compared with 1970, those contemplating a career in psychiatry during the years 1971–1976 could expect substantially lower earnings than most other medical specialists. In fact, in 1973 and 1974 psychiatry was the lowest-paid medical specialty, with family practice (i.e., both general practice and family practice) and pediatrics being slightly ahead of psychiatry. In 1975 and 1976 psychiatry managed to gain some ground compared with family practice and pediatrics but remained substantially behind internal medicine and the surgical specialties. To be truly comparable, income should be tracked for physicians in the same cohort over time to compare relative productivity rates. The American Medical Association data (2) do not allow for this analysis. Subsequent collections of data are necessary to develop a more rigorous analysis.

Another factor to be considered when comparing average income is the influence of the entry of a disproportionate number of physicians into a given specialty in any one year. This situation would occur if situational factors encouraged a large number of new graduates to select a given specialty. Factors that encourage a large number of existing specialists to reduce their practice or otherwise decrease their productivity are also important, for these developments would slow the growth of the average income for the affected specialty. Furthermore, if a significant number of physicians in a given specialty tended to switch after a decline in productivity, this would leave that specialty with a higher average income. There is no reason to believe that a larger number of individuals selected psychiatry as a specialty during the years addressed by this paper. In 1970, 10.3% of all U.S. and Canadian first-year residents were in psychiatry programs, but this figure dropped to 7% in 1974 and 5.6% in 1976.

However, the relative positions of pediatrics and family practice may have been affected by an influx of new graduates in the early 1970s, causing a slowing of income growth rates for those two specialties.

The impact of technology, labor, investments, and the state of the economy are all critical variables when

Presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12–18, 1979. Received May 29, 1979; revised Dec. 13, 1979; accepted Feb. 8, 1980.

The authors wish to acknowledge the helpful comments of Drs. Thomas McGuire and Paul J. Fink.

one attempts to comprehend the changes, both long-term and short-term, observed in any income trend. In 1972 and 1973 wage and price controls for medicine were in effect. According to the Congressional Budget Office, from August 1971 to April 1974 the average annual percentage change for physicians' fees was 3.2%. The impact of the economic stabilization period on psychiatrists' income was basically negative. The most negative year for psychiatry, 1971, was a time when all specialties seemed to be enjoying a positive year. Further; 1971–1973 was a poor period for psychiatry compared with other specialties. These three years are important to consider. It could be assumed that the wage and price controls of 1972 and 1973 had a significant impact on the income of all medical specialties. However, in 1971 psychiatrists experienced a significant decline in income from 1970. What this means is not quite clear, since it predated the imposition of wage and price controls. The cloudiness appears because in 1970 there was a 17.9% increase in the incomes of psychiatrists over 1969; this represents a significant rise in fees in 1969. By 1971 wage and price controls made it more difficult to raise fees significantly, so that psychiatry was basically stuck at the 1969 level. Insurance companies, which ratify "usual and customary" fees, helped keep the fees low during 1971–1973. By 1971 psychiatry began its slide in relation to pediatrics and family practice, as well as the rest of medicine.

One must be careful about drawing cause-and-effect conclusions about the relationship between the income of physicians and the economy. However, it would appear to us that psychiatry is more sensitive to a depressed economy than are the other medical specialties. This might suggest that people view assistance from psychiatrists as more discretionary than most medical care and even a luxury during a period of economic recession.

This finding contrasts directly to studies done by Professor N. Harvey Brenner of Johns Hopkins University (3), which show that admissions to mental hospitals rise in times of unemployment and decrease during periods of economic upturns. Clearly, there are more mentally ill individuals during these periods of economic downswing who are unable to afford private psychiatric care, and there is a shift of psychiatric patients from the private sector to the public sector.

ECONOMIC DISADVANTAGES FOR PSYCHIATRISTS

Psychiatry is both labor-intensive and time-intensive. It has not been able to keep up with high-technology medicine and has not been able to divide its services into discrete technological elements for which there can be individual charges. Perhaps the one exception to this occurs in general hospital psychiatry, where insurance coverage is better and provider and facility charges can be broken down into various units such as individual therapy, group therapy, and milieu therapy.[1] Psychiatrists are paid for their direct time spent with the patient, and this makes psychiatry less profitable than surgery, anesthesiology, radiology, and internal medicine.

TABLE 1
Average Net Incomes of Office-Based Psychiatrists Compared with All U.S. Medical Specialists for 1970–1976[a]

Year	Psychiatrists	Percent Change	All U.S. Specialists	Percent Change
1970	$39,986		$41,789	
1972	39,124	−2.1	47,240	+12.7
1974	41,258	+5.5	51,997	+9.9
1976	47,565	+15.3	59,544	+14.0

[a]Data are from *Profile of Medical Practice* (2).

Further, private health insurance usually continues to place special limits on coverage for psychiatric treatment, especially outpatient psychotherapy. These limits consist of higher copayments, lower numbers of visits, and lower dollar limits than for other illnesses. Fees (usual and customary) paid by third parties have remained fairly stable over time. One economic analysis[2] indicated that in 1973 if the copayment rate for psychotherapy had been 20% across the board, the average fee would have been $74.20 instead of the prevailing fee, which was $35.00. In the rest of medicine third-party insurance has increased the income of medical specialists, so physicians' incomes—by and large—have been able to outstrip the rate of inflation, which since 1970 has been considerable. Physicians earning $33,000 in 1970 would have had to earn $58,000 in 1978 to keep pace with the economic changes caused by inflation and taxes. Psychiatrists have clearly not kept pace with their medical colleagues or with the rate of inflation (4).

The most recent data (for the years 1974–1976) suggest that psychiatry is improving its economic position. Since psychiatry has been placing increased emphasis on peer review and accountability, insurance benefits have slowly but surely expanded in the private sector, and serious consideration is being given to inclusion of psychiatric benefits under national health insurance and expansion of psychiatric coverage under Medicare. If these trends continue, the early 1970s might in fact be considered an aberration in the long-term growth and health of psychiatry.

Productivity factors such as the number of hours of practice per week, the number of weeks of practice per year, the total number of patient visits, and the number of hours of direct patient care per week are important elements in a productivity calculation. In each of

[1]Milieu therapy has been successfully challenged by several insurance companies as a discretely billable item.

[2]T. McGuire: The market for psychiatric services, unpublished paper.

these categories, psychiatry is below the national average for medicine and below both pediatrics and family practice. While it is clear that the average number of total patient visits for psychiatrists should be low, given the 50-minute-hour service unit, the other factors that contribute to an apparent lower level of productivity may either be inherent in the practice of psychiatry or in the work characteristics of those who select psychiatry as a specialty.

Competition from nonmedical mental health professionals has intensified in recent years. In many states psychologists have won recognition as independent practitioners and do not need physician referral in order to receive reimbursement for psychotherapy. Efforts to gain similar recognition are being made by social workers and psychiatric nurses. Success of such efforts would lead to some price or market competition for psychiatrists, although the latent demand for psychiatric and other mental health services is so great that there are more than enough patients to go around. The larger issue is the impact on the financing mechanism of a large supply of practitioners. CHAMPUS data (5) show that clinical psychologists usually charge the same fees as psychiatrists, so that there is no price competition with psychiatrists. Social workers, on the other hand, charge less and price becomes a factor in the supply and demand issue.

In Canada the introduction of national health insurance improved the economic position of psychiatrists. Psychiatric income rose 70% over a 7-year period, compared with an average for all medical specialties of 62%. Yet psychiatry is the lowest-paid medical specialty in Canada. Liptzin (6) concluded, "Psychiatrists simply could not generate the additional or more expensive services that other specialists could."

Some policymakers have asserted that if psychiatric treatments had proven their effectiveness, there could be greater third-party coverage and more value ascribed to these treatments. Although the effectiveness of many medical/surgical treatments (such as coronary bypass surgery) is in doubt, there is excellent third-party reimbursement. The problem, then, is that along with psychiatric patients, psychiatric treatments are stigmatized, given less value, and underfinanced.

One area that requires further study is the impact on the psychiatrist of raising his or her hourly fee. This "fee-countertransference" often takes the form of guilt feelings on the part of psychiatrists, who do not feel themselves worthy of $75–$100 per hour remuneration. Hourly fees (in 15-minute segments) for lawyers, on the other hand, are in the $100–$200 range, and surgeons think nothing of charging several thousand dollars for one operation. These professionals feel that they are entitled to such payments for the services they render. Psychiatric care is more open-ended and a continuous drain of money for patients, and the outcome is less certain. The psychiatrist's relationship with the patient is a key issue, and fees play an important role in the definition and structure of the relationship (7).

A final issue is equity. The highest earnings for psychiatrists are located in the private sector, often in communities with large numbers of psychiatric practitioners, such as Washington, D.C. Currently, most psychotherapy is used by college-educated upper-middle-class white persons.

This pattern of usage is reinforced by the current distribution of insurance coverage. It must be convincingly demonstrated that psychotherapy treatments are valuable and relevant to the lower socioeconomic classes so that expanded third-party coverage through national health insurance would not be a subsidy of the rich by the poor. A recent study of federal employees in Washington, D.C. (8), showed that 26% of patients were grade 9 ($17,000–$22,100) or lower and 59% were grade 12 ($24,700–$32,000) or lower. This would indicate that a substantial number of middle-class individuals use psychotherapy when insurance coverage is adequate.

Psychiatrists' incomes, therefore, are important as a sign of the value of psychiatric care and as one measure of the economics of practice, that is, the incentive related to the distribution of scarce technology and labor in the service delivery system.

Results of Clinical Renal Function Tests in Lithium Patients

BY ROBERT H. GERNER, M.D., JAMES PSARRAS, M.D., AND MICHAEL A. KIRSCHENBAUM, M.D.

Because there have been reports suggesting that patients who receive lithium are at risk for renal damage, the authors carried out extensive noninvasive testing of renal function in 43 patients who had been taking lithium for from 1 to 120 months. Their only abnormal finding was that the urine concentrating ability of these patients was moderately but asymptomatically impaired. They suggest that although patients receiving lithium should be carefully evaluated and tested, there is not enough evidence to justify not initiating or continuing lithium use in patients who might benefit from it.

The use of lithium has revolutionized the treatment of manic-depressive (bipolar) illness and is, without a doubt, the single most effective method of treatment and prevention of this disorder (1), although use of carbamazepine (2, 3) and spironolactone (4) is under investigation. Three decades of experience with lithium have found it to be well tolerated and to have few apparent side effects when given in a well-controlled manner (5). Recent reports of possible serious renotoxicity have cast some doubt on the apparent safety of lithium. Since approximately 1% of the general population has bipolar (manic-depressive) disorder, and a larger number have recurrent unipolar depression that might be responsive to lithium (6), the possibility of serious side effects raises an important public health question. At the heart of all such treatment versus risk questions lies the trade-off of the ratio of another or no treatment to the risk inherent in the treatment.

A wide range of renal side effects associated with lithium have been known for many years. One of the most striking is the incidence of polyuria and polydipsia associated with lithium treatment, which was originally reported by Schou (7). Many other nonpathological effects of lithium on renal physiology have been reported (8–14); these have been reviewed by Jenner and Eastwood (15). More recently, several authors have suggested that lithium therapy may result in chronic, irreversible alterations in renal function and perhaps in structural renal abnormalities shown by biopsy (16–23). However, others have reported no difference in abnormalities obtained by biopsy in patients about to start taking lithium compared with those who had been taking it for an average of 5.5 years (24).

Because these reports suggested a risk to patients receiving lithium, we carried out extensive noninvasive testing of renal function in 43 patients at the Affective Disorders Clinic of the University of California, Los Angeles. Renal biopsy was not done because it carries a morbid risk. We felt it important to determine if there were clinically reliable and safe tests that might differentiate patients at risk for diminished renal function on lithium. In addition, we thought it important to conduct tests that could feasibly be carried out in most patients who are taking lithium rather than concentrate on those tests which require an extraordinary degree of time and technical support.

METHOD

We studied 43 patients (23 women and 20 men aged 17–67). All were bipolar I or II as diagnosed by the Research Diagnostic Criteria (25). Patients had been taking lithium for 1 to 120 months (mean, 26.8 months). All patients were euthymic at the time of urine collection, and none had diabetes, hypertension, autoimmune diseases, or renal disease before starting lithium. Patients were given detailed written instructions and an oral explanation by a physician to facilitate compliance. On day 1 at 7:00 p.m. the patients took their final dose of lithium and then ceased oral intake of food and fluid. A specimen of urine was taken 12 hours later for determination of urine osmolality to assess concentrating ability. The patients then started a 24-hour urine collection. At the end of the collection period, a blood sample was collected to determine lithium level, creatinine, blood urea nitrogen (BUN), uric acid, electrolytes, and osmolality. A spot urine was obtained for amino acid chromatography. Complete history regarding the patient's use of lithium; side ef-

fects; use of other medications, alcohol, and medications known to affect renal function; and medical history was obtained at this time. Glomerular filtration rates were estimated by endogenous creatinine clearance. Ideal creatinine clearance (C_{cr}) for each individual was calculated according to the method of Cockroft and Gault (26) (we used lean body weight to deal with differences in muscle mass that may affect creatinine levels):

$$C_{cr} = \frac{(140-\text{age})\ (\text{lean body weight in kg})}{72 \times \text{blood creatinine (mg/100 dl)}}$$

The ideal creatinine clearance for women was calculated at 90% of that derived using the formula for men. Chemical determinations were performed using standard laboratory techniques.

RESULTS

Glomerular Filtration Rate

Plasma creatinine (normal range, 0.7–1.3 mg/dl) was obtained for 42 of the patients (mean, .97, SEM, .025). Only 1 patient, a husky 25-year-old man who had been taking lithium for 24 months, had a plasma creatinine level greater than normal (1.4 mg/dl). His creatinine clearance was within normal limits (134 ml/minute). Creatinine clearance could be calculated for only 40 patients because of laboratory errors. Three patients were not included because their urine collections were incomplete and they therefore had extraordinarily low creatinine clearances. No statistical differences were noted when the actual creatinine clearances (mean, 93±5 ml/minute) of these patients were compared with their ideal creatinine clearances (mean, 86±4 ml/minute) by group or paired t test. When the ratio of the ideal to the observed creatinine clearance was calculated, 10 patients were found to have a ratio of less than 1, suggesting a decrement in their creatinine clearance. In 8 of these patients the decrement was greater than 10% and the duration of their lithium treatment, which ranged from 1 to 120 months, did not differ from that of the other patients. There was no significant correlation of decrement in creatinine clearance and duration of lithium treatment in these individuals, nor in the group as a whole. The plasma creatinine levels of these patients was normal (range, 0.7 to 1.0 mg/dl). None of these patients had a documented history of lithium overdose, although 1 patient had overdosed on barbiturates and tricyclic antidepressants. No patients in this group had proteinuria.

When the creatinine clearance was calculated by age, the expected decrease with age was observed. However, this age-related decrease was less in our lithium-treated patients than was predicted, and the slope of the observed lithium/age correlation ($r=-.10$) was less ($p<.10$) than the ideal slope ($t=-.68$), showing that lithium did not exacerbate the well-known decrease in creatinine clearance associated with aging.

24-Hour Urine Proteins

Three patients had minimally elevated levels of protein: 1 woman and 2 men (aged 28, 31, and 37, respectively; all had received lithium for 24 months). They excreted 1.24, 1.03, and 1.07 g protein/24 hours, respectively. Creatinine clearances in these patients were not low (actual/calculated ideal: 95/97, 139/105, and 141/71). No other abnormalities were present on any of the other tests except for dehydration osmolality, which was quite low in 2 of the patients (383 and 395 mosmol/liter), while in the 37-year-old man it was 773 mosmol/kg H_2O.

Blood urea nitrogen (normal, 8–20 mg/dl) was slightly elevated in 4 patients, whose BUNs were 21, 22, 23, and 25. All 4 of these patients had normal creatinine clearances and no proteinuria.

Uric Acid

Serum uric acid was slightly elevated in 2 women (6.4 and 8.6 mg/dl) and 4 men (7.5, 7.5, 7.7, and 7.9 mg/dl) (norms: men, 4.2–7.4, and women, 2.7–6.1 mg/dl).

Urine Lysozymes

Urine lysozymes were not elevated in any of our patients (mean, 1.14±.16, norm, 0–4.6).

Amino Aciduria

Urine amino acid chromatography revealed minor elevations in methylhistadine in 2 patients and glycine in 5. In 4 patients who had repeat examinations, no sustained elevations in amino acids in the urine could be detected, suggesting that dietary factors contributed to the original mild abnormal findings.

Maximal Urine Concentrating Ability

As has been reported consistently in the past, our patients appeared to have a defect in maximal renal concentrating ability; their mean urine osmolality was 602 mosmol/kg H_2O (range, 100–965). None of the patients was hypernatremic. There were no significant ($r=-.22$) correlations of urine osmolality by duration of time on lithium.

Lithium Levels

Lithium levels in all of the patients ranged from 0.6 to 1.2 mEg/liter. Two patients who had a history of overdose with lithium had normal values for all tests. Virtually all of the patients had received other psychoactive medications, including neuroleptics, tricyclic antidepressants, and MAO inhibitors.

DISCUSSION

Our findings confirm those of previous investigators that urine concentrating ability is moderately but usu-

ally asymptomatically impaired in patients receiving lithium. This is the only abnormal finding in our patients as a group. We did not find any elevation in urine lysozymes, which may be elevated early in the presence of parenchymal kidney disease, nor did we find amino acids in the urine, which might reflect proximal tubular dysfunction, as in the Fanconi syndrome. Creatinine clearance for the entire group was slightly better than predicted. A few patients had low creatinine clearances (63%–94% of that predicted). Although the most likely reason for these values is inaccurate collection, this finding suggests that a few patients taking lithium may have a decrease in the glomerular filtration rate; this is not necessarily due to lithium, however. The mild proteinuria experienced by 3 of our patients suggests a defect in glomerular permeability, although it was not demonstrated that this was associated with lithium in these patients. We did not find an associated abnormal creatinine clearance in those patients with slightly elevated plasma creatinine or BUN, suggesting that these elevated values were not related to abnormal renal function. All of the patients who had slight elevations of these tests had creatinine clearance levels that were better than expected. There was no relationship between duration of lithium treatment and creatinine clearance or age-related changes in creatinine clearance.

Our findings suggest that noninvasive clinical testing of patients taking lithium does not reveal consistent abnormalities suggestive of seriously impaired renal function. It appears from our limited data that plasma creatinine and BUN alone are not sensitive enough to use as screening tests for patients receiving lithium because they do not correlate well with the slight abnormalities in creatinine clearance or 24-hour urine protein excretion that were observed in a few patients.

Renal biopsy was not warranted in any of our patients. Rather, we feel that those patients who have proteinuria and/or a decrease in their creatinine clearance should continue receiving lithium and have the test repeated to correct for possible collection or laboratory errors. If the findings are still abnormal, the patient should have a more extensive evaluation and be followed at intervals of 6 months to 1 year. It is not possible at this time to make a judgment on how frequently such tests should be performed on individuals who do not have an initial abnormal value. It is very important to note, however, that the calculation of the ideal creatinine clearance must be done with care because in many individuals with low muscle mass normal uncorrected creatinine clearance values may be lower than those commonly perceived as normal.

Because of the considerable difficulty in obtaining consistent and reproducible urine collections, we have the following recommendations for collection of urine for protein and creatinine clearance that may facilitate outpatient as well as inpatient screening. We suggest that urine collection be done while the patient is at the clinic or office, much as they would be for a glucose tolerance test. Valid calculations for creatinine clearance and urine protein concentration can be gathered by having patients come to the clinic, void, and collect all subsequent urine for the following 4–6 hours. Encouraging patients to drink ample amounts of fluid during this time will result in a greater urine output and more accurate results. All of our patients were quite cooperative with the study; no one stopped taking lithium because of fear of kidney problems. After testing and having the results explained to them, virtually all of the patients expressed relief and gratitude at the interest that was being taken in them and the seriousness with which their condition was being viewed.

In conclusion, we feel that the tests used, which include many that are generally available as well as specialized tests, did not reveal gross clinical impairment in renal function in patients who had been receiving lithium for from 1 to 120 months. We did not find a decrement in function by duration of time on lithium in any of the tests. Although caution and careful psychiatric evaluation of all patients taking lithium need to be maintained, there does not at present appear to be sufficient evidence to justify not initiating or continuing lithium use in patients who might benefit from it. Until the issue is more fully resolved, it may be prudent to obtain, if feasible, creatinine clearance and urinary protein values in patients before or soon after initiating lithium treatment and to retest them 1 year later and periodically thereafter. We agree with Vestergaard (27) that it would not be wise to alter current treatment practices of manic-depressive patients on the basis of preliminary reports of renal toxicity until large-scale investigations are available that will help the physician weigh the benefits and hazards of lithium treatment. Future studies should control for the many other medications most bipolar patients have been exposed to and, additionally, should consider possible renal effects of manic-depression per se.

Board Certification Anxiety

BY FRANKLIN G. MALESON, M.D., PAUL J. FINK, M.D., AND HOWARD L. FIELD, M.D.

The authors discuss how stress influences the candidate's capacity to effectively prepare for and fully demonstrate his or her abilities in the oral examination in psychiatry given by the American Board of Psychiatry and Neurology. They highlight subtle misconceptions about examiner priorities, attitudes, and evaluation methods and note common errors that reflect both anxiety and these misconceptions. They offer some advice and information to aid the candidate in coping with these examination difficulties.

Published reports (1-3) in addition to personal accounts suggest that the average candidate takes the American Board of Psychiatry and Neurology certification examination in a state of intense and occasionally disorganizing anxiety. Endless anecdotes attest, such as keys being lost, pipestems crunched, and eyeglasses broken in the simple process of wiping. In the examination, word reversals, amnesias for fundamental information, the assumption of bizarre interviewing postures, and the like are common. One author somewhat hyperbolically describes this state as a "pseudodelirium" (1).

Although some candidates may have neurotic difficulties in taking examinations, the conscious and generally shared sources of oral Board examination anxiety are well known. Preparation requires major personal sacrifice, which candidates and their families are loath to repeat. Pride, reputation, and academic and professional opportunity are often considered to be at stake. These anxieties are brought into a test situation that offers its own unique stresses. Oral examinations have a potential for subjectivity and lack of uniformity in grading. The candidate may fear that his patient will

be highly unusual or uncooperative and that the resulting difficulties will be marked against him. He may fear that the examiners will be capricious, sadistic, or unduly focused on their own narrow clinical or research interests. In short, a helpless anticipation that "anything can happen" prevails. A recent call for a moratorium on the oral examination by more than 200 APA members reflects these concerns (4).

As Board examiners, we have witnessed a variety of performance impairments seemingly derived from stresses specific to the examination situation.[1] Successful candidates are not immune, and it is likely that some who are unsuccessful would be found qualified were it not for examination-specific difficulties. Most of us know colleagues whom we regard as highly competent and yet who have at one time failed or conditioned Part II. Most examiners are familiar with the seemingly adequate candidate whose entire performance disintegrates after he is stumped by one or several questions. About 18% of the candidates who take Part II pass on a second or later attempt (5). Undoubtedly some of these successful repeaters correct genuine clinical deficiencies identified in the first examination—an ideal examination function. It is likely, however, that a large number of successful repeaters do not become more competent in any substantive way but rather develop better test-taking strategies, practice more under simulated test conditions, or have lower levels of anxiety as a result of knowing better what to expect. These speculations have been supported by preliminary analysis of free response data in a recent APA survey designed by the 1977–1978 Ad Hoc Committee to Implement the 1976 Referenda on Psychiatric Certification.[2]

The following information and remarks, offered to aid the prospective candidate by highlighting some typical misconceptions and stress reactions that interfere with maximal demonstration of capability, pertain to the make-up and modus operandi of the examining teams, the preparation process, and the psychological and interactional phenomena in the actual test situation (especially the 30-minute question and answer period when the candidate feels most vulnerable).

THE EXAMINER'S PERSPECTIVE

In the instructions to examiners the following paragraph appears: "Avoid discussion of abstract, obscure matters of questionable importance. If areas are uncovered in which the candidate is not informed, do not dwell exclusively on these topics. Find out what else he may know. . . . Do not restrict the examination to one type of philosophical orientation" (6).

All the examiners we have observed have essentially followed this instruction and failures do not result from the candidate's ignorance of "minutiae." Occasionally a highly technical question is asked but rarely out of context. Sometimes examiners ask such a question to find redeeming areas of special competence in a candidate whose performance is otherwise poor. For example, a candidate who was weak in his discussion of differential diagnosis and hospital management of his manic patient was asked about the significance of platelet monoamine oxidase activity. Although this was a seemingly narrow point, he seemed to know about psychopharmacology and was given an opportunity to demonstrate a deeper knowledge in this area.

Examiners are very concerned with *how* a candidate thinks about a patient, i.e., how he weighs and sorts clinical evidence. Some candidates experience difficulty organizing and articulating case summaries, presenting differential diagnoses, and discussing treatment; rambling and vagueness in these areas have been noted elsewhere (1). To some extent such difficulties may be related to anxiety and may abate after the candidate has had practice in simulated examinations.

It is helpful for a candidate to avoid a guarded or reticient posture and to talk openly about what he knows and how he has reached his conclusions; for example, "The patient's vagueness and history of head trauma made me suspect an organic brain syndrome, but I was surprised when he did so well on mathematical and memory tests." Similarly, there appears to be no reason for a candidate not to mention areas that he may have neglected to explore during the course of his patient interview. This at least demonstrates an awareness of what was missed, which is obviously preferable to the examiner's having to extract such information or concluding that it would never have occurred to him. (Some typical examples include eliciting a family history of mania with a depressed patient and exploring amphetamine use with evidence of a transient paranoid psychosis.) It is also advantageous for the candidate to acknowledge areas of unfamiliarity, to comment on issues felt to be controversial, and to request clarification of an examiner's question when necessary. What examiners are seeking is competence (3, 7, 8) not brilliance or some hypothetically perfect interview.

IMPROPER EMPHASIS IN PREPARATION

The candidate must enter the examination with broad expectations of the range of psychopathology he may encounter and the kinds of issues he will be asked

[1]Dr. Fink has been an assistant and associate examiner for nine years. Dr. Field has been an assistant examiner twice, and Dr. Maleson once. They have observed and conducted numerous examinations.

[2]S.K. Quick, Associate Director, Office of Education, American Psychiatric Association, Washington, D.C., 1979 (personal communication).

to discuss. With the prospect of seemingly endless possibilities, some may have subtly and unconsciously narrowed their mental set, much to their disadvantage. A number of candidates seem surprised to encounter patients who are not overtly psychotic, brain damaged, or addicted; it appears they are not prepared to consider less profound degrees of impairment. One candidate was startled when he belatedly realized that he had not included hysterical conversion in his differential diagnosis, in spite of highly suggestive symptoms and his familiarity with this diagnostic entity. Another candidate, who incorrectly assumed that her patient was hospitalized, wasted more than 10 minutes of precious interview time in a confused misinterpretation of the man's history and never regained her composure after an examiner told her about the patient's outpatient status. (This last anecdote confirms the wisdom of the candidate orienting himself fairly early, in a graceful fashion, to the specifics of the patient's overall situation.)

Many candidates do not seem geared to apply such familiar topics as psychodynamics, principles and problems of psychotherapy, and hospital management to their patients. In contrast, almost all are well versed in the use of psychotropics, particularly lithium, and biological psychiatry in general. Insufficient expertise in the more purely psychological matters could certainly account for some of this trend. Nevertheless, most psychiatrists have had considerable exposure in their training and daily activities to nonbiological issues, so it is possible that these matters are harder to talk about, particularly for those who are not very articulate. Or some candidates may harbor an unwarranted expectation of examiner bias against psychodynamics and psychotherapy, as if these were unfashionable. They may thus be caught by surprise or perhaps even fear being drawn into statements that will prejudice the examiners against them. Others may be overconfident about their ability to verbalize ideas in familiar areas and prepare disproportionately in areas in which they feel vulnerable to factual error.

It is useful to test and practice the presentation of one's skills in multiple clinical reference frames: psychological, biological, diagnostic, therapeutic, and prognostic. Difficulties in discussion of fundamental issues are a much greater source of failure than the feared questions about psychiatric obscurities.

THE EXAMINATION CLIMATE

Another instruction to examiners states, "There is no place for sarcasm or humor at the candidate's expense, or attitudes of condescension or cool hostility. Make every effort to put the candidate at ease and to encourage his best performance" (6).

Although it is likely there are examiners who are unwilling or unable to adhere to these guidelines, our experience and that of others (1, 9) indicate that most examiners struggle for clarity and fairness in their questions and privately empathize with the candidates. Many primary examiners are not far removed from their own stressful experiences as candidates and note a recrudescence of their anxieties during their orientation. They report feeling quite uncomfortable when their fellow physicians stand terrified before them. Candidates with such overwhelming anxiety are a minority but are by no means rare, and it is often difficult to calm them.

The problem is intensified by the requirement that feedback and reassurance, the responses so needed by the especially anxious candidate, be minimized during the examination in order to avoid excessive steering or suggestion of answers. In addition, any adverse examiner comment during the examination, however delicately worded, risks inflaming existing anxiety. Even when a candidate appears to be doing well to one examiner, the need to consult other examiners before arriving at a final grade requires caution in any offering of reassurance. There may not be general agreement among examiners about a candidate's performance and to reassure someone who later fails would only heighten postexamination resentment.

Thus, with many subtle variations, most examiners attempt the difficult task of being friendly and at the same time pointedly neutral. Some could be described as inscrutable; others limit feedback to barely perceptible nods of the head or other cautious agreements. It is easy to understand how the anxious candidate in search of positive signs can interpret such strained postures as cool hostility, condescension, or even impending failure and why it has been a source of resentment and criticism (3, 10). If the candidate does not anticipate a great deal of examiner responsiveness, he may be less flustered by its absence.

This unavoidable limitation of candidate-examiner rapport was exemplified by the reluctance of a number of candidates to revise statements or diagnoses that they themselves had made untenable by their later remarks. It is not always easy for examiners to decide whether this phenomenon reflects deficient clinical ability or an examination artifact, such as fear of being tricked by the examiner, stress-induced rigidity, or a notion that any retraction reveals a fatal indecisiveness. In these situations the candidate was usually not given the benefit of the doubt.

THE EVALUATION PROCESS

Different examiners tend to agree on the scores of the same candidates, although the backgrounds and fields of interest of examining team members are varied. Private practice, administration, teaching, and research are all represented. Expertise ranges from psychoanalysis to psychopharmacology (7). Although dif-

ferent examiners can obviously assess some areas more critically than others, it is clear that the examiner team functions with a satisfactory operational definition of competence.

The candidate is not likely (at least on a statistical basis) to be discriminated against by assignment to one team or another. Over the years there has been good team-to-team scoring agreement, with approximately the same number of candidates passing regardless of the leadership of the team and the clinical setting in which the examination takes place (7).[3]

Candidate performance is treated conscientiously during the evaluation process (1, 9). Examiners usually do not differ in grading by more than 1–2 points, a difference that is crucial only when it occurs around the scores of 70 and 75 (the minimum grades for conditioning and passing, respectively). In such marginal cases the several examiners who have observed the candidate typically spend extra time and energy in vigorous and sometimes agonized debate. This provides a measure of safety through a system of checks and balances (1, 9).

When examiners confer, views appear to be stated with independence and mutual respect. In general, the senior examiners, who usually spend no more than 10 or 12 minutes with any candidate, are willing to defer to the primary examiner when this is warranted. For example, one candidate had been doing quite well until he attempted to pretend knowledge about the contributions of some major researchers whose work pertained to his case. At this awkward moment the chief examiner of the section entered the room. Observing the confused and labored discussion he soon departed, convinced that the candidate would fail with little debate. During the evaluation, the other examiners explained that despite this apparent bluff the candidate's overall performance was good; he passed the examination.

Our remarks about the grading procedure will not satisfy those who question the existence of any uniformly acceptable or meaningful standard of excellence, at least as measured by such an examination (3, 11, 12). We hope that our description of the essential fairness of the grading process within the existing testing conditions will provide some reassurance to the candidate.

[3]R.I. Shader, Boston, Mass., 1978 (personal communication).

ANXIETY OR LACK OF CLINICAL COMPETENCE?

We hope that some of our comments will not be interpreted as useful strategems for the creation of a facade of competence by poorly qualified candidates. It is doubtful that any strategy could carry a truly weak candidate very far. Regardless of what one may think of the validity of the test as a measure of safe clinical competence, in order to pass it, there is no substitute for good training, extensive study, and practice under simulated test conditions. Our advice should aid the prospective candidate in coping with the stresses of the test situation so that his or her abilities are demonstrated to maximum advantage. Such a salutory effect would also aid the examiners. As examiners, we have often been in the dilemma of trying to distinguish between the effects of anxiety and insufficient clinical ability and have had the unwelcome and saddening task of flunking some candidates who we suspected were more knowledgeable than they were able to demonstrate.

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Anaclitic Depression in a Three-and-One-Half-Month-Old Child

BY THEODORE J. GAENSBAUER, M.D.

Since the classic studies of Spitz (1), it has been generally assumed that anaclitic depression does not occur in infants before the age of six months. Infants younger than this age have been thought to lack the maturity and specific attachment to the mother necessary to produce a depressive picture in reaction to her loss (2, 3). The infant described below, who had been referred to the author for a psychosocial evaluation by her social services careworker, has brought this assumption into question. The information to be presented in this report is based on social service and hospital records, including psychiatric evaluations of the parents; interviews with the mother, both foster mothers, and social service and hospital personnel; and direct observation of the infant.

Case Report

Jenny was the product of a normal pregnancy and delivery. Although her mother treated her at times more like a doll than a person, she was breast-fed, actively cared for, and almost constantly in her mother's presence. Jenny's father was affectionate but had a severe temper. When 2 weeks old, Jenny was found by her pediatrician to have fractured her arm; at 7½ weeks a small bruise was noted during a well baby clinic checkup, and at 3 months she was hospitalized with a second broken arm and a nondepressed skull fracture. On each occasion, the injuries occurred while Jenny was alone with her father. In spite of this severe abuse, neighbors and health care professionals who saw Jenny before her hospitalization and observers in the hospital described Jenny as a happy, highly sociable baby who smiled readily and showed no evidence of withdrawal. Bonding and eye contact with her mother were noted to be good. During Jenny's hospitalization, the only observable effects of the recent abuse were visual hypervigilance, a tendency to squirm when held by unfamiliar people, and increased fussiness, which was no doubt partly related to pain from her injuries.

After a 5-day hospitalization, Jenny was taken to a foster home. This resulted in an abrupt weaning, loss of contact with her mother, and a significant decrease in attention from those caring for her. The foster mother provided Jenny with minimally adequate physical care, but she left Jenny in her crib for long periods without stimulation.

During the next 3 weeks, Jenny and her mother were brought together by the Department of Social Services on three occasions. Her mother commented later, "Each time I saw her, the more out of touch she seemed to be." The first visit, 10 days after Jenny's transfer to the foster home, confirmed the positive relationship between Jenny and her mother. An onlooker noted that Jenny immediately recognized her mother's face and "lit up like a Christmas tree" with broad smiling and excited activity. One week later Jenny seemed more subdued during her mother's visit. Her mother observed that she cried more easily, was less active, had lost interest in her toys, and smiled less readily.

The third visit took place when Jenny was 3 months, 25 days old; she and her mother were evaluated at our play-

room laboratory.[1] When they were brought together, Jenny's mother and a caseworker noted that Jenny failed to greet her mother positively and that it was difficult to get Jenny's attention. Jenny's appearance during the one-hour evaluation was that of a depressed child. Her hunched-over posture gave the impression that it was an effort for her to hold up her head. She seemed apathetic and disinterested in her environment and could not be engaged in play. Smiling was almost absent. She was easily upset and fussed when she was overstimulated. Jenny's facial expression during most of the session ranged from subdued to definitely sad. An independent videotape analysis of Jenny's facial expressions, utilizing objective scoring systems for the facial expression of discrete emotion (4, 5), confirmed the presence of a sad facies; specific facial components of sadness that were present included a drawing together and raising of the inner corners of the eyebrows and a downturning of the corners of the mouth. The rater observed the most clear-cut facial expressions of sadness during those times when her mother was present. The rater also noted that throughout the visit Jenny avoided eye-to-eye contact with her mother; gaze aversion was particularly unmistakable when her mother returned to the room after a brief separation. Viewers of the videotaped session, including several experienced clinicians, have consistently described Jenny's affective state as "sad," "pitiful," and "painful to watch."

Immediately following the playroom visit, at the request of the first foster mother, who felt overburdened by 3 other foster children, Jenny was placed in a new foster home with a warm and sensitive foster mother. The first day Jenny seemed subdued with a "kind of unhappy look." Her new foster mother also observed that Jenny tended to avoid face-to-face interaction. However, Jenny responded quickly to the optimal mothering during the next couple of days; she began to smile more readily and vocalized in response to her new foster mother's attention.

Five days after Jenny was transferred to her new foster home Jenny visited her mother at her mother's apartment. Jenny was now 4 months old. During the visit, Jenny was apparently quite fussy and her mother had great difficulty in soothing her. When she was returned to the foster home, the foster mother noticed that Jenny acted "coldly, like she was mad." The subdued facial expression, disinterest in people, gaze aversion, and lack of smiling that had characterized Jenny's first day in the foster home persisted for the remainder of the evening. She awoke that night crying, whereas the previous two evenings she had slept through the night.

Two weeks after her initial visit Jenny was evaluated again in our laboratory when she was 4 months, 8 days old. On this occasion she was evaluated with her new foster mother. Jenny's appearance at this time reflected a normally responsive 4-month-old child. She was engaging, alert, and curious about her environment; she smiled frequently and scored well on developmental testing. Her sad facies had disappeared. She still showed intermittent gaze aversion and a propensity to fuss when overstimulated, although these occurred in much more subtle forms.

Discussion

Jenny's history provides evidence that a depressive picture is possible in children at a much earlier age than has previously been assumed. Pathognomonic signs of anaclitic depression that were present in her case included a sad facies, withdrawal, apathy, psychomotor retardation, absence of pleasure, and a tendency toward irritability and distress (6). Jenny's mood disturbance was not a transient one; it emerged over a 3-week period and persisted for several days after adequate caretaking was reestablished.

The precipitating events for Jenny's depression, consistent with those previously described for anaclitic depression, involved a triple loss: separation from her actual mother, abrupt weaning, and affective and stimulus deprivation. The crucial factor in Jenny's depression was the loss of the mothering function rather than the specific loss of her mother. This is indicated by the prompt improvement in Jenny's depressive picture after her caretaking environment improved. Yet the evidence suggests that the loss of Jenny's relationship with her mother contributed to her depression. Jenny showed a clear and positive recognition of her mother during their first visit after their separation. Only as time passed did she develop depressive-withdrawal symptoms and specific avoidance of her mother's face. Further evidence for specificity in Jenny's reaction to the loss of her mother includes the finding that during the first laboratory visit Jenny's sad face was specifically associated with her mother's presence and the fact that after her visit with her mother following her placement in the second foster home there was a transient reoccurrence of the depressive-withdrawal picture.

It is likely that the sight of her mother's face awakened in Jenny, at some level of recognition, the affectively painful experience of her loss, resulting in sadness and fussiness whenever her mother was present. If this hypothesis is correct, Jenny's avoidance of eye-to-eye contact with her mother could be explained as a defensive measure used to avoid experiencing the depressive-affective state (7).

Haloperidol and an Unrelated Sudden Death

BY ROBERT E. SMITH, M.D., NANCY N. LOW, M.D., AND HENRY A. NASRALLAH, M.D.

When sudden, unexpected deaths occur in psychiatric patients, the psychotropic medications the decedent had been receiving are often suspected of causing or contributing to the fatality. If the autopsy report does not fully explain the cause of death, there is further suspicion for a drug-related death. As a result, neuroleptics have been implicated in some sudden, unexpected deaths. In those cases when an autopsy does not support a definitive cause of death, the postulated mechanisms for neuroleptic-induced deaths include cardiac toxicity, vasodilatation and hypotension, hyperpyrexia, and the production of unspecified neurologic dysfunction.

We report below the case of a sudden, unexpected death in a young man who had received only moderate doses of haloperidol for control of extreme agitation. An autopsy was performed, but the cause of death was not determined until a detailed reexamination of the patient's heart was undertaken. The autopsy finding prevented this case from being another sudden death with no demonstrable cause of a patient who was taking neuroleptics.

Case Report

Mr. A, a 30-year-old married man, was first admitted to the hospital because of obsessions with homosexual thoughts. Multiple stresses preceded and surrounded the onset of his illness. As an outpatient, Mr. A had treatment that included psychotherapy and the administration of antipsychotic medications, which gave him some relief. By the time of his admission, however, his clinical condition had deteriorated to a severely anxious and, at times, psychotic state. While hospitalized, Mr. A was treated with antidepressants and psychotherapy. He was discharged after 8 weeks with his condition improved but tenuous. At the time of his discharge he was instructed to take 200 mg/day of amitriptyline h.s.

Three days after his discharge Mr. A was readmitted because of severe anxiety, poor sleep, suicidal ideation, and increasing impulses to harm his wife. In the hospital he continued to be very agitated. The amitriptyline was discontinued on the day he was admitted, and antipsychotic medication was reinstated. However, his condition continued to worsen, and he developed catatonia with bizarre posturing. These symptoms alternated with periods of extreme agitation. Because he made repeated attempts to injure himself during his periods of agitation, it was necessary to intermittently use four-point restraints. Throughout his hospitalization Mr. A was fully oriented, with an intact sensorium.

Two days after his admission the treating physicians noted clonic-type movements in his upper extremities. A neurological consultation ruled out seizure activity. Four-point restraints continued to be used during his periods of extreme agitation.

At 9:00 the next morning it was noted that Mr. A had respiratory difficulties. His heart rate was very rapid and his blood pressure was unmeasurable. An examination demonstrated no evidence of upper airway obstruction. Mr. A developed cardiopulmonary arrest, and resuscitation was immediately instituted. A cardiac team arrived and implemented full resuscitative measures, including placement of an endotracheal tube and intravenous pacemaker. Despite 45 minutes of ceaseless efforts, however, Mr. A's heart failed to respond and he was pronounced dead. During the 3-day period before Mr. A's sudden, unexpected death he had received a total of 47 mg of haloperidol. On the day preceding his death he was given 25 mg of haloperidol.

A preliminary autopsy examination revealed congestion and edema of the patient's lungs, liver, spleen, and brain. These are nonspecific findings, and although consistent with acute congestive heart failure, they do not explain the cause of death. Further pathology studies of the heart were undertaken to rule out the possibility of a conduction tissue defect or other disease that would not be grossly evident, and this examination determined the pathologic basis for Mr. A's death.

The left anterior descending and circumflex coronary arteries showed focal atherosclerotic narrowing to 50% loss of internal diameter. The coronary circulation was right dominant with focal narrowing to nearly complete obstruction of the right coronary artery from 4 cm to 8 cm from its ostium. Step sections through the right main coronary artery at the level of the most obstructed areas showed severe atherosclerotic narrowing with only a slit-like lumen remaining.

Microscopically, the upper and middle septum showed large areas of stretched myocardial fibers with first-, second-, and third-order waviness. The fibers were variably eosinophilic, and a rare fiber showed flocculated cytoplasm. However, cross striations were present and nuclei were only minimally pyknotic. The waviness extended into the area noted grossly to be thickened beneath the aortic valve ring. The conduction tissue of the AV node and immediately below it showed fragmented small fibers with pyknotic nuclei and congested small blood vessels. Some contraction bands were present. The muscle fibers high in the interventricular septum were enlarged with a tendency to whorl. These are diagnostic findings of early myocardial ischemic change (1, 2).

Mr. A's death, which occurred during acute congestive heart failure, was caused by acute myocardial ischemia with severe segmental coronary atherosclerosis present.

Discussion

Sudden, unexpected deaths are not unique to the psychiatric patient population. The age-specific rate for sudden, unexpected death in apparently healthy individuals aged 20 years to 39 years is estimated to be 47 deaths per 100,000 population (3). Several studies have examined the causes of sudden, unexpected deaths in apparently healthy, young adults (3, 4). In one study (4) the most frequent causes of death were asymptomatic coronary heart disease and untreated infections. Twenty-eight percent of these patients died from coronary heart disease with or without recent occlusion. Another study (3) found that 61.4% of all sudden deaths were due to coronary heart disease. Because coronary heart disease is the leading cause of sudden death, it must be carefully ruled out before one reports a death as having no demonstrable natural cause and before one questions whether previously administered medications contributed to the death in an unspecified manner.

There are numerous problems inherent in the pathology of sudden death due to coronary heart disease. It has been estimated that routine autopsies underreport the correct proportion of occlusive coronary artery disease by more than half (5). However, even when occlusive arteriosclerotic disease is found, it is reported as an incidental finding unless evidence for myocardial ischemia or infarction is also present. Definitive histologic evidence may be difficult to find in many cases of sudden death because of the rapidity of the terminal event. Recent advances in the histopathological findings in early myocardial ischemia (1, 2) now permit a diagnosis of early myocardial infarction to be made. Such was the case in this patient. We suggest, therefore, that previously reported sudden, unexpected deaths in patients receiving neuroleptics may represent cases of occlusive coronary heart disease with myocardial infarction.

Psychiatric patients with asymptomatic coronary heart disease may be at an increased risk for sudden death because of agitation and heightened arousal secondary to their psychotic state (6). Neuroleptics may be indicated to reduce this risk. Haloperidol for sedation has been reported to be safe in moderate dosages (5 mg i.m. every 4 hours to 6 hours) for patients with acute myocardial infarction (7). Thus, it appears that haloperidol does not further impair a compromised coronary circulation.

To our knowledge, the literature contains only one report of a sudden, unexpected death in a patient receiving haloperidol and no other psychotropic medication (8). An autopsy of that patient reported no demonstrable cause of death. The authors suggested that an idiosyncratic response to haloperidol may have occurred. A similar conclusion may have been reached in this case if a reexamination of the decedent's heart had not been undertaken. Because asymptomatic coronary heart disease is the leading cause of sudden, natural death in young adults, this diagnosis must be carefully ruled out in any sudden, unexpected death involving a patient receiving psychotropic medication.

Deficient Prolactin Response to Morphine in Depressed Patients

BY IRL EXTEIN, M.D., A.L.C. POTTASH, M.D., MARK S. GOLD, M.D., DONALD R. SWEENEY, M.D., PH.D., DAVID M. MARTIN, AND FREDERICK K. GOODWIN, M.D.

The discovery of opioid receptors and endogenous opioid peptides (endorphins) in the brain (1) has kindled interest in the possible role of endorphin systems in psychiatric disorders (2, 3). The analgesic, euphoric, and calming effects of exogenous opiates suggest that decreased functional activity in endogenous opioid peptide systems could be linked to the pathophysiology of depression. Opiate receptors and endorphins are widely distributed in limbic and hypothalamic areas thought to be involved in depression. Endogenous opioid peptides may modulate noradrenergic and dopaminergic neuronal systems that are implicated in the etiology and pharmacotherapy of depression.

There are anecdotal reports from the prepsychotropic era of the efficacy of opiates in treating depression. Researchers have observed significant depression in opiate addicts after detoxification. Some of these patients have been successfully treated with opiates and tricyclic antidepressants, suggesting that opiate discontinuation resembles the discontinuation of effective psychopharmacologic maintenance treatment. Administration of β-endorphins has ameliorated depressive symptoms in some patients (3). These data support the hypothesis that endogenous opioids influence the maintenance of pathological mood states.

We used a neuroendocrine challenge paradigm to study in vivo endogenous opioid systems in depressed patients. The normally pronounced increase in serum prolactin produced by morphine (4) was markedly blunted in patients with major depressive disorder.

Method

We studied 5 male and 5 female inpatients diagnosed as having major depressive disorder (9 unipolar patients and 1 bipolar patient) according to Research Diagnostic Criteria (5). Their mean age was 44±5 years; the range was 22–62 years. The control group consisted of 2 normal volunteers and 4 inpatients (4 women and 2 men) with a primary diagnosis of personality disorder. Their mean age was 33±8 years; the range was 19–62 years. All subjects gave written informed consent to participate in the study. Seven of the patients with major depression had used psychotropic medication during the 6 weeks before the study. Most of this use consisted of brief trials at low doses: 5 patients received neuroleptics alone; 2 patients received neuroleptics plus antidepressants. (During this time the control subjects had remained drug free.) Patients received no other medication except flurazepam for at least 1 week before the study. The patients fasted overnight; an indwelling venous catheter was inserted at 8:30 a.m. and kept open with normal saline. At 9:00 a.m. we infused 5 mg of morphine sulfate over 60 seconds through the catheters. We obtained small samples of blood through the catheters before and 30, 60, 90, 120, and 180 minutes after the morphine infusion for assay of serum prolactin in duplicate by radioimmunoassay (2). We calculated the maximum prolactin response for each patient by subtracting the baseline prolactin from the maximum prolactin level after morphine infusion. Values are expressed as mean ± SEM. Statistical significance of differences between means was determined by two-tailed t test. Patients filled out an adjective checklist self-rating form before the morphine infusion and at the time of each blood drawing.

Results

The control subjects and the depressed patients did not differ significantly in age or sex distribution. Morphine infusion produced marked, significant increases ($p<.05$) in serum prolactin 30, 60, 90, 120, and 180 minutes after infusion in the control subjects. There was no significant difference in the increase in prolactin levels in the patients with personality disorders compared with the normal volunteers. In the patients with major depressive disorder morphine infusion produced only small, nonsignificant increases in serum prolactin (see table 1). Mean baseline prolactin levels of 9.0±1.4 ng/ml in the control group did not differ from those of 10.5±1.9 ng/ml in the depressed group. Mean prolactin levels in the depressed group were significantly lower than those in the control group at 60 ($p<.01$), 90 ($p<.02$), 120 ($p<.02$), and 180 ($p<.05$) minutes (see table 1). The mean maximal prolactin response of 7.2±2.7 ng/ml in the depressed group was significantly lower than that of 31.9±9.5 ng/ml in the control group ($p<.01$). There was no significant correlation between maximal prolactin responses and baseline prolactin levels. The morphine infusion produced

only small, nonsignificant subjective antidepressant and antianxiety effects in both the depressed and control groups.

Discussion

Both exogenous opioids and endogenous opioid peptides are potent stimulators of secretion of the pituitary hormone prolactin in animals (6) and man (2, 4, 7). Morphine in the dosage range we used has been reported to produce large and reliable increases in serum prolactin in normal subjects (4). Prolactin secretion is controlled in part by the dopaminergic tuberoinfundibular tract, which exerts an inhibitory effect over the secretion of prolactin (8). Serotonergic neurons have a stimulatory effect on prolactin secretion and other neurotransmitters and neuromodulators, including norepinephrine and epinephrine, have been reported to modulate prolactin secretion as well (8). Researchers have located opioid receptors on dopaminergic neurons (1). When these opioid receptors are activated, they inhibit the dopaminergic tonic inhibition of prolactin secretion. Such opioid receptor activation would therefore allow increased secretion of prolactin after administration of opioids (6).

Thus the absent or blunted increase in serum prolactin occurring after morphine infusion in our patients with major depressive disorder may reflect abnormalities in central endorphin, dopamine, serotonin, or other neuroregulatory systems. Possible abnormalities in endorphin systems that could account for a blunted prolactin response to morphine in major depression include an opioid receptor deficit, an excess of endogenous opioid antagonist, or elevated endorphin levels with compensatory down-regulation of opioid receptors. Although there was no significant difference in baseline prolactin levels between the control subjects and the patients with major depressive disorder, subtle changes in baseline prolactin secretion or diurnality might partially explain the blunted prolactin response to morphine exhibited by the patients with major depressive disorder. Halbreich and associates reported increased secretion of prolactin in depressed patients during the afternoon and evening (9). An increased prolactin secretion at some time of the day in the patients with major depressive disorder could conceivably have decreased the sensitivity of the prolactin system to stimulation. Possibly the use of psychotropic medication by some of the depressed patients in the 6 weeks before the study may have influenced their prolactin response to morphine. If this were the case, however, one would probably expect a significant difference between mean baseline prolactin levels of patients with major depressive disorder and those of control subjects, or correlation between maximal prolactin responses and baseline prolactin levels. We observed neither of these. Researchers should explore other factors that might influence prolactin response to morphine in depression, such as corticosteroid or thyroid axis abnormalities or pharmacokinetic changes.

While we observed significant miosis, we noted only a small, nonsignificant subjective antidepressant effect in the depressed patients. This lack of antidepressant response to morphine parallels the lack of neuroendocrine response in depressed patients. Perhaps higher doses of morphine or other opioids are needed to stimulate prolactin secretion in depressed patients than in control subjects. Preliminary work shows elevation of serum prolactin in depressed patients after infusion of 5 mg of methadone, which is about twice as potent as morphine (10). Investigators should continue to explore the role of endorphin systems, including the possible antidepressant effects of exogenous opioids and endorphins and their analogues in depressed patients.

Localized Right Cerebral Hemisphere Dysfunction and Recurrent Mania

BY MARTIN R. COHEN, M.D., AND RICHARD W. NISKA, M.D.

Krauthammer and Klerman (1) recently reviewed the literature for reports of mania secondary to medical and/or pharmacological antecedents. They used operational diagnostic criteria for mania and excluded patients with a previous history of affective disease or accompanying symptoms of acute organic brain syndrome. The authors, who were able to find numerous cases meeting their criteria for secondary mania, concluded that mania should be considered a syndrome with multiple causes. Do these case reports also reveal information about the particular mechanism or neurophysiology involved? Most episodes occurred following a generalized disruption of cerebral functioning. In light of previous reports, we feel the following case report is suggestive of a specific mechanism. To our knowledge, this is the first report in the English literature of recurrent mania associated with localized cerebral psychopathology.

Case Report

Mr. A, a 59-year-old, right-handed man, had been in good health until the fall of 1974 when he suffered a subarachnoid hemorrhage. Evidence of a right temporal lobe hematoma was obtained from angiography, radionuclide scan, and CT scan. He initially manifested a left hemiparesis and left homonymous hemianopsia, but gradually improved so that by the time he was discharged 3 weeks later he had only minimal neurologic residua.

In February 1977 Mr. A was admitted for psychiatric care after an 8-week history of irritable mood and constant waking activity. His sleep time had become shortened and fragmented. His speech was described by relatives as loquacious, loud, grandiose, and tangential. He had begun driving his car at high speeds, buying expensive commodities, and investing his business capital irresponsibly. A mental status examination revealed that Mr. A was elated and irritable and had abortive episodes of tearfulness, with pressured speech and flight of ideas. No delusional or hallucinatory material could be elicited. His cognitive functions, including memory, orientation, serial sevens, and general fund of information, were found to be intact. He was diagnosed as suffering from manic-depressive illness, manic type, and lithium carbonate treatment was begun. Mr. A's condition gradually improved during the next 15 days, at which time he was discharged as euthymic. His lithium level was 0.93 mEq/liter.

During an outpatient follow-up visit that spring, Mr. A manifested some relapse of symptoms, which correlated with poor medication compliance. However, his symptoms abated 2 months later and the lithium was discontinued.

Mr. A was symptom free until July of the following year, when he was hospitalized after 3 to 4 weeks of symptoms similar to those that occurred in his first episode. Over a 3-week period he again responded to lithium and was discharged with a serum lithium level of 1.14 mEq/liter. While he was euthymic, neuropsychometric testing revealed that Mr. A had an average intelligence with intact verbal abilities, verbal memory, and abstract reasoning, but he had impaired visual perception, nonverbal sequencing, and nonverbal memory.

Approximately 1 year and 2 months later Mr. A was admitted to the hospital with his third episode of mania, which had apparently developed over the preceding 2 months. A repeat EEG was consistent with a residual focal right hemisphere lesion. He was again treated with lithium and gradually improved during the next month. Mr. A attained a peak lithium level of 1.62 mEq/liter. As an outpatient, he continued to do well while taking lithium.

Each of Mr. A's three episodes of psychopathology met both the Feighner and associates' (2) and Spitzer and associates' (3) criteria for mania. Despite extensive interviewing of Mr. A as well as many family members, we could find no history of affective disorder in him or his family.

Discussion

We believe Mr. A's mania is not coincidental to his cerebral dysfunction. The onset of mania at age 61 without a personal or family history of affective disorder is suggestive of a causal relationship (1, 4). Mr. A also met Krauthammer and Klerman's operational criteria for secondary mania.

In the English literature there are four reports of mania secondary to localized cerebral lesions (5–8). A striking similarity exists between our report and the case described by Rosenbaum and Barry (5). Their patient was undergoing neurosurgery when his right temporal lobe was traumatized and its anterior two centimeters resected. In the succeeding months, the patient developed a left homonymous hemianopsia and jacksonian seizures in his left arm. An EEG revealed a dysrhythmia involving the right posterior temporoparietal area. Five months later the patient developed mania, which was responsive to lithium. A later attempt to discontinue lithium resulted in recurrence of the mania.

Oppler (6) reported a case of mania that abated with the removal of a parasagittal meningioma involving the right frontoparietal area. Following the operation, there was transitory weakness of the left arm and leg. Stern and Dancey (7) reported a case of unremitting chronic mania in a patient who, at autopsy,

was found to have a tumor occupying the right diencephalon.

Most recently Jamieson and Wells (8) reported a patient with four mass lesions in the right occipital, temporal, and parietal lobes. Although this patient was manic before surgery, it is notable that following partial right parietal occipital lobectomy the patient developed left-sided weakness and left unilateral neglect. The patient's performance IQ was substantially more affected than the verbal IQ. This patient's mania also responded to lithium. There was no recurrence of the mania after lithium withdrawal, but the patient died 2 to 3 months later.

Evidence reviewed by Flor-Henry (9) suggests that the organization of the cerebral mood system in dextrals may be lateralized to the right hemisphere. We can now add that our case, as well as the four previously reported cases of mania secondary to localized cerebral impairment, demonstrates predominant right hemisphere dysfunction. As Flor-Henry has speculated (9), perception of our own movement, so necessary for biological survival, may be an important psychophysiological component in the generation of our moods. These case reports support a close association between motility and visuospatial defects and secondary mania.

For diagnosis and treatment, justified emphasis has been placed recently on dividing mania into functional (primary) versus organic (secondary) categories. However, the etiological distinction may be somewhat arbitrary. Dalen's study (10) of hospitalized manic patients showed that those patients who apparently lacked a hereditary predisposition had had a greater frequency of exposure to perinatal events that involved a risk of brain damage and a greater frequency of EEG abnormalities. Our patient, as well as other secondary manics, showed a typical time course and response to lithium. He manifested the classic pattern of remission without medication and periodic recurrence.

These reports suggest that it may be possible to develop an animal model of mania secondary to surgically or chemically induced right temporoparietal dysfunction. Development of this model would require awareness of a latency period between cerebral insult and the onset of mania.

Haloperidol Excretion in Human Milk

BY RONALD B. STEWART, M.S., BARRY KARAS, AND PHILIP K. SPRINGER, M.D.

Information concerning the excretion of specific psychotropic drugs in human milk is limited, although much concern for the potential hazards has been expressed in the literature (1–4). Psychotropic drugs are used frequently during pregnancy to treat nausea and vomiting and after delivery to treat anxiety, depression, and, occasionally, psychotic episodes. In this paper we present a case report documenting excretion of haloperidol in human breast milk and discuss the implications of this finding.

Case Report

Ms. A, a 33-year-old woman, entered our hospital with the complaint, "I killed my baby." This, in fact, was not true. Five days before her hospitalization she reportedly engaged in bizarre behavior that consisted of screaming and lying on the floor. She was diagnosed at this time as suffering from a major depressive disorder with psychosis. Ms. A had experienced a brief psychotic episode 1 year earlier and another one 1½ years earlier.

Five weeks before her hospitalization Ms. A had given birth to a girl, and she had breast-fed the infant until she was admitted to the hospital. Ms. A wished to continue nursing her child after she was discharged so she expressed milk from her breast three or four times daily during the hospitalization to maintain lactation. Because of her psychotic symptoms we prescribed 20 mg/day of haloperidol and increased the dosage as needed.

We were unable to find any definitive information concerning the excretion of haloperidol in human milk, so we decided to collect samples of Ms. A's breast milk and measure it for levels of haloperidol. Ms. A expressed the milk by hand; we collected samples in vacutainer blood tubes and then froze them. Concentrations of haloperidol were measured at the National Psychopharmacology Laboratory in Knoxville, Tenn., by using a gas chromatograph equipped with a nitrogen detector.

After 6 days of haloperidol therapy with a mean daily dose of 29.2 mg, 5 ng/ml of haloperidol were detected in Ms. A's breast milk. This level was obtained 11 hours after her haloperidol dose. On day 12, 9 hours following a 12-mg dose, her breast milk levels were 2 ng/ml. From day 13 to 19 we prescribed 7 mg/day of haloperidol (2 mg in the morning and 5 mg in the evening). We reduced the dose to 2 mg/day on day 20, and the next day we discontinued the drug. Concentrations of haloperidol levels in the breast milk were not detectable 3 days after the last 7-mg dose. These breast milk levels are similar to the therapeutic plasma levels that have been observed in pharmacokinetic studies in man (5).

Discussion

To our knowledge, this is the first report of haloperidol excretion in human breast milk. One study showed that levels of haloperidol in the milk of lactating cows and ewes were approximately 65% of those levels found in the animals' serum (6).

The pharmacokinetics of haloperidol have been extensively studied in man and animals (5, 7, 8). Haloperidol is eliminated primarily by metabolism in the liver and no active metabolites are produced. Bioavailability of haloperidol after oral administration is estimated to be 60%, and a serum half-life from 12.6 hours to 22.0 hours has been observed. Serum concentrations of haloperidol reach a steady-state level after approximately 6 days of treatment, and levels may vary up to tenfold in individuals given the same dose. Steady-state serum levels of haloperidol were shown to range from 3 ng/ml to 20 ng/ml in a study of 11 patients who were each given 6 mg/day of haloperidol (5).

Levels of haloperidol in the breast milk of our patient were 5 ng/ml after an average dose of 30 mg/day and 2 ng/ml following a 12-mg dose. This is a very small concentration of haloperidol in the milk. An infant normally ingests from ½ to 1½ liters of milk daily (9). Using this approximation, we calculated that an infant could receive a maximum of 0.0075 ng/day of haloperidol. The effect of these small concentrations of haloperidol on an infant is not known. Therefore, physicians should carefully assess the need for antipsychotic drug therapy in a mother nursing her infant.

Oculogyric Dystonia in Tardive Dyskinesia

BY HENRY A. NASRALLAH, M.D., NICHOLAS J. PAPPAS, AND RAYMOND R. CROWE, M.D.

Dystonia is an acute extrapyramidal side effect of neuroleptic drug treatment. In one study (1) it was found that approximately 10% of the patients receiving neuroleptic drugs developed dystonia, which is usually associated with such high-potency neuroleptics as haloperidol and the piperazine phenothiazines. Dystonia usually occurs shortly after neuroleptic drug ingestion: 90% of patients experience dystonia within the first 4 days of drug treatment (1), or after an increase in drug dosage. It is characterized by tonic contraction of any skeletal muscle or muscle group, commonly involving the face, mouth, neck, and extraocular muscles in a painful and frightening oculogyric dystonic reaction. Dystonia usually occurs in young males and mainly in the initial phase of neuroleptic treatment.

We report here the appearance of an oculogyric dystonic reaction in a chronically medicated patient with severe tardive dyskinesia of several years' duration. This was our first observation of these symptoms in a patient with tardive dyskinesia, and to our knowledge such an occurrence has not been reported. Because the mechanism of dystonia and tardive dyskinesia is hypothetical and rather vague, the coexistence of these two symptoms and the circumstances leading to the coexistence may shed some light on the underlying neuropharmacological correlates of the symptoms.

Case Report

Mr. A, a 42-year-old single man, was admitted to the hospital for management of severe buccolingual tardive dyskinesia, which he had had for several years. It was gradually interfering with his speech, eating, drinking, and even breathing. He had been diagnosed as suffering from chronic paranoid schizophrenia at age 22, when he was first treated for psychosis. Mr. A was repeatedly hospitalized over the next 20 years, with the same diagnosis, and was maintained almost continuously on neuroleptics—chlorpromazine, thioridazine, trifluoperazine, fluphenazine, and haloperidol. Buccolingual dyskinesia was first noted at age 30. At age 40 Mr. A was hospitalized for the first time for management of his tardive dyskinesia, mainly severe mouth opening and tongue movements. He failed to show any improvement with a test dose of 2 mg of i.v. physostigmine, a cholinergic agonist, but he showed partial improvement with 1250 mg/day of sodium valproate, a γ-aminobutyric acid agonist, without a neuroleptic. However, Mr. A became psychotic again and manifested many first-rank symptoms; he was placed on 800 mg/day of thioridazine with good results.

During the current hospitalization, Mr. A received 800 mg/day of thioridazine and continued to suffer from severe tardive dyskinesia. He was given a trial of up to 40 mg/day of diazepam and improved somewhat for about 2 weeks. Diazepam was then gradually discontinued, and we decided to give him a trial of reserpine. However, Mr. A asked that another neuroleptic be substituted because thioridazine had made him impotent for the past several months. Thioridazine was gradually discontinued and 15 mg/day of trifluoperazine was started; we increased the dose to 50 mg/day within 5 days. Mr. A's involuntary movements did not change during this transition, and .1 mg of reserpine t.i.d. was started. Three days later Mr. A suddenly developed an oculogyric dystonic reaction at night; that day he had received trifluoperazine, 10 mg orally t.i.d. and 20 mg h.s., and reserpine, .25 mg orally t.i.d. and .75 mg h.s. Mr. A's eyes were fixed in an upward gaze and his neck was stiff, but he continued to have his buccolingual involuntary movements. Immediately 50 mg of i.v. diphenhydramine were given to Mr. A; he had prompt relief of his dystonic symptoms and, according to him, a transient subjective relief of his dyskinetic movements. During the next 36 hours Mr. A had two mild recurrences of upward gaze and still neck, which were promptly relieved with 25 mg–50 mg of i.v. diphenhydramine. He continued to take 50 mg/day of trifluoperazine for the next 3 weeks and up to 6 mg/day of reserpine, with no further dystonic reaction and with partial improvement of his tardive dyskinesia symptoms.

Discussion

The mechanism of neuroleptic-induced dystonias is still unknown, and there is no animal model of dys-

tonia. However, due to the efficacy of anticholinergic drugs in treating dystonia, it has been suggested that dystonia may be due to the sudden decrease in dopaminergic activity and the relative increase in cholinergic activity following the dopamine-blocking effects of neuroleptics. Reversal of dystonia with dopamine agonists such as methylphenidate (2) and apomorphine (3) also supports this hypothesis. However, other drugs such as caffeine (4), diazepam (5), meperidine (6), and barbiturates (7) have been reported to relieve dystonia as well. Hypocalcemia and hypomagnesemia have also been shown to predispose patients to dystonia (8).

Another hypothesis by Marsden and associates (9) proposes that dystonia may be due to an increase, rather than a decrease, in dopamine activity due to the initial and transient compensatory increase in dopamine synthesis and turnover at the beginning of neuroleptic therapy. Support for this view also comes from Garver and associates (10). They found that dystonia appeared after the red blood cell concentration of a single dose of neuroleptic had peaked and was decreasing, possibly reflecting a decreased blockade of dopamine receptors.

The possibility that dystonia may be due to increased dopamine activity is of particular significance in this patient because his dystonia was superimposed on tardive dyskinesia. It is also believed that tardive dyskinesia is caused by dopamine hyperactivity and relative cholinergic hypoactivity (11) due to dopamine receptor supersensitivity secondary to a chronic dopamine receptor blockade by neuroleptics. Is it possible, then, that dystonia is the acute, transient, extrapyramidal manifestation of increased dopamine hyperactivity through a rebound increase in dopamine release? Is it possible that at the same time tardive dyskinesia is the chronic, persistent extrapyramidal manifestation of increased dopamine hyperactivity through the increased number of dopamine receptors, i.e., hypersensitivity? If so, then could acute dystonia early in the course of neuroleptic treatment predict future predisposition to tardive dyskinesia?

In our patient the addition of reserpine to trifluoperazine 2 days before the dystonic reaction is consistent with Marsden's hypothesis of dopamine hyperactivity preceding dystonia. Reserpine is a neuroleptic that releases dopamine until the neuronal stores are depleted. Thus during the first 2 days our patient took reserpine, there was probably a massive increase in synaptic dopamine concentrations in the presence of dopamine receptor hypersensitivity, which was only partially blocked by trifluoperazine. This could have resulted in a sudden, exceptionally high dopamine activity above that which exists, hypothetically, in tardive dyskinesia. This sudden surge in dopamine hyperactivity may have allowed the dystonic symptoms to emerge against the background of tardive dyskinesia.

Finally, reserpine given alone is known to produce various extrapyramidal side effects but not dystonia, even when reserpine is given in high dosages (9). On the other hand, neuroleptics that block dopamine receptors can produce dystonia even in very small dosages. This suggests that a dopamine receptor blockade may be an important step in the neurophysiological mechanism of dystonia. It would be quite important to note whether reserpine given with or without a neuroleptic that blocks dopamine receptors, such as trifluoperazine in our patient, may have a differential effect on dystonia and/or tardive dyskinesia.

Family Experiences of Self-Mutilating Patients

BY JACQUELINE CARROLL, CHARLES SCHAFFER, M.D., JAMES SPENSLEY, M.D., AND STEPHEN I. ABRAMOWITZ, PH.D.

Parental deprivation is commonly noted in the childhood histories of self-mutilating patients (1). Feelings of isolation or separation anxiety often trigger self-mutilation (2–4), and some patients seek physical or sexual contact when tension mounts.

Recently, investigators have linked physical abuse during childhood to later episodes of self-mutilation (4–6). In two cases Green found a relationship between physical abuse and self-destructive behavior in children (6, 7). Roy (5) also found that more self-mutilating patients recalled excessive physical punishment in childhood than control subjects did.

The outward expression of anger may be severely restricted or punished in the families of self-mutilating patients, so that as children these individuals learned to turn their aggressive feelings inward (8). Other childhood histories of self-mutilators note eating problems (2, 3), accident-prone behavior (3, 7), family violence (1), and open displays of sex and aggression by the parents (4).

Most of the early data on the family backgrounds of self-mutilators are based on clinical impressions and case studies. Interview-based research has focused on present behavioral features, population characteristics, and management issues. Through a structured interview we explored aspects of early experience implicated but not yet systematically investigated in the self-mutilation literature.

Method

Our study included 14 self-mutilating patients and 14 nonmutilating, nonsuicidal control subjects from the same public psychiatric population. All self-mutilating patients reported at least one deliberate act of self-inflicted injury that was nonsuicidal in intent, and most had a history of several similar incidents. Their mean age was 28.1 years, with a range of 21–41 years. Six self-mutilators were inpatients (nonpsychotic at admission). Ten of the 14 self-mutilators were women, reflecting the sex ratio reported for this population (9). The control group was matched for age, inpatient/outpatient status, and sex.

Two of us (J.C. and C.S.) interviewed the subjects (one of us is a third-year clinical psychology graduate student, the other a third-year resident in psychiatry). We elicited information about aspects of behavior and history noted in the literature as relevant for self-mutilating, suicidal, or violent patients and nominally categorized responses.

Results

The results of Fisher exact probability tests indicated whether the criterion variables were more characteristic of the self-mutilating patients than of the control subjects. We found significant between-group differences for major separations before age 10, family violence, physical abuse, and anger prohibition by the family. Differences were not significant for birth order, sexual abuse, symptoms of triad for violence, accident proneness, eating problems, socioeconomic class, or family psychiatric history. In every instance, however, there was a trend consistent with a clinical formulation about self-mutilation.

Major separations from parental figures occurred more frequently in the childhood histories of self-mutilating patients. More self-mutilators than control subjects lost at least one parent before the age of 10 ($p<.05$).

Other coded data less amenable to reliable classification suggested a disparity in self-mutilators' parental relationships. Self-mutilating patients described a good relationship with one parent and a sharply negative relationship with the other more often than control subjects did.

Violent behavior or physical fighting occurred more often in the families of self-mutilators than in the families of control subjects. Two self-mutilating patients and 3 control subjects reported some family violence, while 10 self-mutilating patients and no control subjects reported excessive family violence. Self-mutilating patients were disproportionately represented among those who reported either some or excessive violence in the home during childhood ($p<.01$).

We also found a strong relationship between physical abuse by parents and self-mutilation. Four self-mutilating patients and 1 control subject recounted some or moderate abuse, while 8 self-mutilating patients and no control subjects described excessive physical abuse. Self-mutilating patients reported physical abuse strikingly more often than control subjects did ($p<.005$).

Sexual activity with an older family member tended to occur more often in the childhood histories of self-mutilators. Three female self-mutilating patients and 1

female control subject experienced some sexual abuse, while 2 female self-mutilating patients and no control subjects described excessive sexual abuse.

The self-mutilating patients differed from the control subjects in regard to how anger was handled at home. Thirteen self-mutilating patients and 2 control subjects stated that expressions of anger were not allowed in their families, 1 self-mutilating patient and 9 control subjects stated that expressions of anger were sometimes allowed, and 3 control subjects stated there were no prohibitions against expressing anger in their families. More self-mutilating patients than control subjects reported strong restriction of anger in their families ($p<.005$).

Discussion

The higher frequency of major separations from parents experienced by self-mutilating patients as children supports the notion that separation anxiety and the threat of abandonment are significant themes. This is consistent with reports that a threatened or actual separation from an important relationship can precipitate self-mutilation (2–4).

The high incidence of family violence reported by the self-mutilating patients suggests disharmony in parental as well as child-parent relationships. The sheer extent of the family violence supports the theory that intrafamilial hostility precipitates the self-mutilating syndrome. Another precipitating factor was physical abuse during childhood, which empirical research has only recently related to mutilation (5, 6).

All but one of the self-mutilating patients were abused as children, either physically or sexually; prohibitions against expressing angry feelings may have led these individuals to seek other ways of coping with intense feelings. A conflictual formulation consistent with the data is that parental hostility fosters development of a punitive superego that, under stress, overwhelms ego defenses and triggers self-mutilation. Typically, self-mutilation is followed by a sense of calm, relief, and decreased tension and thus may promote a reintegration of ego defenses. The lack of maternal handling in early childhood reported by self-mutilating patients (3) also suggests a preconflictual component. Self-mutilators may come to associate physical abuse with contact that satisfies the need for physical touching and attention; the need for contact may override the unpleasant sense of pain or the self-mutilators may associate pain with need satisfaction and thus not experience it as pain.

We can also view self-mutilation in terms of a self theory, in which the impulsive self-destructive act becomes an attempt to overcome intense "depletion anxiety," i.e., fear of fragmentation or destruction of the self. Narcissistic patients who have been deprived of gratifications required for the development of a cohesive self may exhibit such behavior (10).

We recommend that researchers define the self-mutilating syndrome more precisely and conduct studies that incorporate nonmutilating suicidal control subjects and methods of subclassifying self-mutilating patients according to the type and the extent of self-injury.

Tinnitus in Imipramine Therapy

BY JOHN RACY, M.D., AND E. ANN WARD-RACY, M.D.

Tinnitus (ringing in the ears) is a well-known side effect of certain medications (1, 2), but it is rarely reported in psychotropic drug use. The 1979 *Physician's Desk Reference* lists tinnitus as the last among neurologic side effects of tricyclics, yet we found no mention of it in any of the standard reference books on psychopharmacology (3–7). Our thorough search of the literature failed to reveal a single reference. In a report comparing two tricyclics, Melitracen and imipramine, Biros and associates (8) mentioned tinnitus as a side effect of Melitracen but not of imipramine. (Melitracen has not been marketed and is currently unavailable.) In 1960 Barker and associates (9) reported two cases of transient deafness in patients receiving imipramine.

Although the results of our literature search would lead us to recommend dropping tinnitus from the formidable list of tricyclic antidepressant side effects, our recent experience with four patients suggests otherwise.

Case Reports

Case 1. Ms. A, a 37-year-old woman, came to the clinic with manifestations of neurotic depression. She gave no indication of psychosis or any suggestion of a schizophrenic disorder. Ms. A had never received psychoactive drugs. Her therapist (E.A.W.-R.) prescribed imipramine, 50 mg/day. After 1 week of this regimen, Ms. A reported that ringing in her ears had started 2 to 3 days after she had begun taking imipramine. The tinnitus was so unpleasant that Ms. A did not want to continue treatment. When Ms. A's therapist persuaded her to continue taking the imipramine at the lower dose of 25 mg/day, her tinnitus stopped. Her clinical state improved, and she was maintained on the same dosage.

Case 2. Rose, a 15-year-old girl, exhibited predominantly depressive symptoms, with some elements suggestive of a schizophrenic disorder. Her therapist (E.A.W.-R.) prescribed imipramine on a graduated regimen of up to 150 mg/day to treat her depression. When Rose's imipramine dose reached 150 mg/day, she complained of ringing in her ears. Her medication was then reduced to 125 mg/day and the tinnitus disappeared. She responded favorably and has been maintained on that dosage.

Case 3. Ms. B, a 30-year-old woman, had had marital conflicts and suffered from severe anxiety and depression. Although she exhibited no evidence of psychosis, Ms. B was highly suspicious and concerned about people who might eavesdrop on her therapy sessions. At a later point her therapist (J.R.) prescribed imipramine. Ms. B responded partially to 100 mg/day and her therapist determined that she needed more medication. When he increased her dosage to 150 mg/day, Ms. B began to complain of nausea and a buzzing sound in her ears. When he reduced her medication to 100 mg/day, Ms. B's nausea and tinnitus subsided, but she again became depressed. Her therapist attempted to find a therapeutic level, increasing Ms. B's dosage by 10-mg increments. At 120 mg/day Ms. B's tinnitus and nausea returned. She achieved clinical improvement with 110 mg/day and suffered no further tinnitus.

Case 4. Mr. A, a 31-year-old man, exhibited low self-esteem, anxiety, anger, and progressive depression, with some borderline features. His therapist (J.R.) prescribed imipramine during the course of his psychotherapy. Its efficacy in relieving Mr. A's depression remained uncertain. While receiving 150 mg/day of imipramine Mr. A complained of distinct ringing in his ears. When the medication was reduced to 75 mg/day, the ringing was still present but somewhat milder. Eventually Mr. A's therapist discontinued imipramine and substituted desipramine at a dosage of 100–150 mg/day. Mr. A's tinnitus did not return and he found the medication helpful.

Discussion

Tinnitus may not be as rare a side effect of tricyclic therapy as would appear from the literature. The fact that our patients were able to continue with and profit from such therapy (either on a reduced dose of imipramine or with a substitute) suggests that this side effect is not a serious impediment or contraindication to tricyclic use. Tinnitus is very distressing to patients and must be controlled. The ringing in the ears described by our patients was typical and bore no resemblance to hallucinations. We found that reducing the dosage of imipramine was usually sufficient to control the tinnitus.

Amitriptyline in Human Breast Milk and the Nursing Infant's Serum

BY TED F. BADER AND KARIN NEWMAN

To our knowledge, there have been no reports documenting the amount of amitriptyline found in the breast milk of women taking amitriptyline chronically or the amount of amitriptyline in the serum of their nursing infants. In this paper we describe such a patient and document the excretion of amitriptyline and its metabolite, nortriptyline, in human breast milk. A serum measurement was also taken of the nursing infant, and no amounts of amitriptyline or nortriptyline were found.

Case Report

Ms. A, a 36-year-old mother of one child, had been taking amitriptyline for 10 years to control her depression. Her usual dose, 150 mg/day was decreased to 100 mg/day when her second pregnancy was discovered. She continued this dose for the 7 months before the birth of her child, a girl weighing 2660 grams. Because Ms. A had suffered severe postpartum depression after the birth of her first child and she desired to breast-feed this child, it was decided that she should continue taking the lower dose of amitriptyline, 100 mg/day h.s.

In order to determine if the drug or its metabolite was accumulating in the mother's breast milk or the infant's serum, two sets of measurements were made to screen for detectable quantities of amitriptyline and nortriptyline in the breast milk (table 1). The first set of measurements was taken 6 weeks after Ms. A had begun breast-feeding her infant. When levels of amitriptyline and nortriptyline were discovered in her breast milk, a second set of measurements was repeated 11 days later; this time the infant's serum levels were also measured. Plasma samples were collected into heparinized vacuum blood collection tubes; care was taken not to allow the serum to come in contact with the stoppers. Breast milk samples were collected and stored in a plastic container. The serum and breast milk samples were stored under refrigeration at 4° C until measured. If samples were to be analyzed later than 3 days after being drawn, the serum was extracted and frozen at −20° C. All samples were analyzed within 10 days. Measurements of drug levels were performed by gas-liquid chromatography mass spectrometry as described by Biggs (1). This method of measurement is sensitive to plasma levels as low as 10 ng/ml. After analysis of the data, known amounts of amitriptyline were added to the breast milk samples to determine whether it was possible to completely recover the drug from the breast milk; the drug was recovered and our method of measurement verified. Ms. A gave informed consent for the study.

TABLE 1
Concentrations of Amitriptyline and Nortriptyline in Mother's Serum and Breast Milk[a] and Infant's Serum

Source	Hours Since Drug Ingestion	Concentrations (ng/ml) Amitriptyline	Nortriptyline
First test			
Mother's serum	15	141	86
Breast milk	16	151	59
Second test			
Mother's serum	14	83	59
Breast milk	14	135	52
Infant's serum		0	0

[a]The mother received 100 mg/day of amitriptyline h.s.

Discussion

In a comprehensive review Ayd (2) reported that there were no published reports on the excretion of nortriptyline and only one published report on the secretion of amitriptyline in human breast milk. In a study by Eschenhof and Rieder (3) no detectable amounts of amitriptyline were found in the breast milk of six women after they received a 25-mg or 50-mg dose of amitriptyline; however, the method of measurement used in the study was sensitive only to 100 ng/ml.

The amounts of amitriptyline and nortriptyline were approximately equal in our patient's breast milk and serum, which indicates that these drugs are probably passed from serum to breast milk in a passive manner.

Equal levels of imipramine and desipramine in serum and breast milk have also been reported (4), even though the patient had taken imipramine and desipramine for only 16 days.

Our finding of undetectable amounts of tricyclic in the nursing infant is reasonable. If we assume the infant received a liberal intake of breast milk, say 1000 cc/day, and if we look at the highest amount of amitriptyline concentrated in Ms. A's breast milk, 151 ng/ml, the baby would ingest only 150 μg/day or 50 μg/kg per day. This figure is still much smaller than the mother's dose of 1.5 mg/kg of amitriptyline.

On the basis of this clinical study it was recommended to the mother that she continue breast-feeding her child if she so desired. A more general recommendation cannot be made from one case report. Nonetheless, in the absence of other data, this report represents preliminary reassurance to nursing mothers because amitriptyline did not accumulate in one nursing infant.

In order to make a rational decision about the use of drugs during breast-feeding, it is not sufficient to find detectable but nonpharmacological amounts of a drug in breast milk. The sine qua non of such a decision must rest upon taking measurements in many nursing infants whose mothers are receiving the drug. This case report is an initial step in gathering such knowledge about amitriptyline.

Psychopharmacological Precautions in the Right to Refuse Medication

BY ROY B. LACOURSIERE, M.D.

The right of involuntarily treated mental patients to refuse medication is being progressively established and delineated (1–4). Although this right may enable a patient to refuse any medication, I will discuss primarily in this paper the psychotropic medications neuroleptics, antidepressants, and lithium. In general this right states that psychotropic medication cannot be forced upon a nonconsenting person being involuntarily treated for psychiatric problems except in an emergency, adjudication of incompetency, or sanction by a properly constituted reviewing body. A right to refuse medication applies with even more force to voluntarily treated persons.

If one accepts a right to refuse psychotropic medication, the responsibility that this right entails also has to be accepted. The following discussion identifies several psychopharmacological precautions, and therefore responsibilities, that need to be considered in the exercise of this right to refuse medication.

Many psychopharmacological issues have been addressed in the legal cases and other publications on the right to refuse psychotropic medication, including discussions on the efficacy of such medication and its adverse effects, such as tardive dyskinesia. However, other important psychopharmacological issues have not received much attention and need to be considered by the courts, mental health bar, and treating personnel. Mental health personnel are more aware of the precautions that need to be taken when using psychotropic drugs, but a reminder may encourage such professionals to keep these precautions before our legal colleagues.

Three issues relating to psychotropic drugs are discussed below: the therapeutic time lag that occurs from the time drug therapy is initiated until therapeutic effects develop; the deterioration time lag that occurs from the time drugs are discontinued until symptom recurrence or exacerbation may be noted in previously drug-responsive patients; and the medical effects (excluding tardive dyskinesia) that occur after abrupt medication withdrawal.

Therapeutic Time Lag

Some patients will improve adequately without psychotropic medication, but for many others neuroleptics, antidepressants, or lithium will be part of the optimum therapeutic recommendation; sometimes more than one of these agents will need to be prescribed. There is a considerable time lag before the optimum therapeutic effects of these medications are achieved. For instance, although neuroleptics can have immediate sedating effects, their optimum antischizophrenic effects on hallucinations, delusions, and disordered thinking may take several weeks. Significant effects from antidepressant medication may take 2–3 weeks to develop, and lithium may not be optimally effective for 1 week or longer. Therefore, persons who refuse such medication, then begin to take it at a later date should not be expected to respond rapidly, except in the limited ways discussed above.

This therapeutic time lag could also mean that a severely suicidally depressed person who was initially a candidate for antidepressant medication but exercised his or her right to refuse the medication might later become a more appropriate candidate for ECT, especially by the time consent for treatment was obtained from the court or other reviewing body. Under these circumstances ECT would be a more rapid and safe treatment in the patient rather than having the patient wait an additional 2 weeks or more for significant response to antidepressant medication. Generally, the exercise of the right to refuse medication will, for many patients, prolong the period of dangerousness to self and/or others and the length of hospitalization.

Deterioration Time Lag

When patients who have been responsive to psychotropic medication then exercise their right to refuse further medication, they will often have an analogous time lag before psychiatric deterioration occurs—if it does occur. The deterioration time curves are less predictable than the therapeutic time curves. A few schizophrenic patients deteriorate seriously and dangerously within a few days after neuroleptic withdrawal, but others function adequately for several months or longer, or even indefinitely (5, 6). Similar time lags occur when patients who are responsive to the medication are withdrawn from antidepressants and lithium, although the percentage of these patients who deteriorate may not be as high as the percentage of schizophrenic patients who stop taking neuroleptics and deteriorate.

These time lags obfuscate our ability to assess the therapeutic and long-term legal effects of decisions made by individuals, courts, or reviewing bodies to exercise the right to refuse psychotropic medication. Patients who show no immediate dangerousness to themselves and/or others or other deleterious effects after their medication is withdrawn may show such effects during the following days or weeks. By then the patient may have been discharged.

This does not mean, of course, that patients cannot be withdrawn from psychotropic medication, but it does mean that precaution should be used by the courts and others in doing so and in assessing the effects of such medication withdrawal in this context of the right to refuse medication. The 1978 case of *Rennie v. Klein* (4) is highly illustrative in this regard. Concomitant with Mr. Rennie's changing acquiescence and refusal to use medication and the court's related interventions, his behavior fluctuated widely and he was at times seriously disturbed and dangerous.

Medical Effects of Abrupt Withdrawal from Psychotropics

A variety of medical symptoms can occur in the few days following the abrupt withdrawal of neuroleptics from patients who have taken them for several weeks or longer; highly sensitive patients may have withdrawal symptoms after only 1 or 2 weeks of medication. I will not discuss tardive dyskinesia because it has already received considerable attention in the literature on the right to refuse medication. Symptoms that are of concern here include nausea and vomiting, stomach pains, restlessness, insomnia, and headaches. These withdrawal symptoms can occur after neuroleptics are discontinued whether or not antiparkinsonian agents are taken concomitantly and are simultaneously and abruptly withdrawn. In a number of studies withdrawal symptoms occurred in 18%–75% of patients after neuroleptics were stopped, with symptoms occurring on the average in about 50% of the patients (7). Although the symptoms are often mild to moderate in severity and usually resolve without sequelae, they can be very severe (7, 8).

Medical withdrawal effects are more clearly established for neuroleptics and for antiparkinsonian agents that are often taken concomitantly with neuroleptics, but they also occur with tricyclic antidepressants (9, 10). Such effects have not been of concern after the abrupt withdrawal of lithium.

The courts, the mental health bar, and treating personnel must use precaution when dealing with previously medicated patients who are now exercising their right to refuse medication and are being removed from tricyclic antidepressants, neuroleptics, and antiparkinsonian medications, which are often taken concomitantly with neuroleptics. It is recommended that such medication be withdrawn gradually over 1 or 2 weeks and that withdrawal symptoms be treated when indicated, e.g., antacids for stomach irritation.

Discussion

In this paper my primary purpose has not been to enter into the legal or psychiatric arguments for or against the right of voluntarily and involuntarily treated persons to refuse psychotropic medication un-

der certain circumstances. Rather, my discussion focused on precautions that should be taken in this context because psychotropic medications have a therapeutic time lag, deterioration time lag, and can cause medical effects on abrupt withdrawal. If we include these precautions in our considerations on this right to refuse medication, a little less human misery may be produced.

A Case Report of Anorexia Nervosa and Gaucher's Disease

BY MILTON K. ERMAN, M.D., AND GEORGE B. MURRAY, M.D.

Anorexia nervosa is a disorder of body image and eating habits seen most frequently in adolescent females. Research diagnostic criteria for the syndrome include refusal to maintain a minimal normal body weight, weight loss of at least 25% of original body weight, distorted body image, intense fear of becoming obese, absence of known medical or psychiatric illness that could account for the weight loss, and amenorrhea in females (1).

Gaucher's disease is an inherited metabolic disorder that occurs most often in Jewish families and is characterized by a deficiency of the lysosomal enzyme glucocerebrosidase (2). Three subtypes have been described. The most common is Type 1 or adult non-neuronopathic Gaucher's disease. It produces hepatosplenomegaly, pancytopenia, and erosion of the cortices of the long bones, has a variable course, and may remain undiagnosed until late in life. Type 2, the infantile neuronopathic form, leads to multiple developmental abnormalities, usually apparent by the sixth or seventh month of life, with a mean survival of nine months (2). Juvenile Gaucher's disease, or Type 3, is characterized by multiple central nervous system abnormalities, including mental deterioration, behavior disorders, psychoses, and abnormal EEGs. Although the disease generally manifests itself in childhood, some adults with this subtype have been reported (2).

We report a patient whose Gaucher's disease initially manifested itself with psychiatric symptoms. To our knowledge, this is the first adult case reported in which investigation of an apparent psychiatric illness led to the diagnosis of Gaucher's disease.

Case Report

Mr. A, a 28-year-old single white Jewish man, was referred to the Massachusetts General Hospital for an evaluation of unexplained weight loss and weakness in his left arm and leg. He reported a weight loss of 22.5 kg during the 6 months before his admission.

The admission physical examination revealed that he weighed 41.4 kg, showed marked cachexia, had lanugo, and had a resting pulse of 55 beats/minute. Hematologic abnormalities included a hematocrit of 24.8% and a platelet count of 50,000. Shortly after Mr. A was admitted, it was noted that he had peculiar attitudes toward food, and psychiatric consultation was requested.

Mr. A requested dietetic foods, professed a dislike for carbohydrates, and was concerned that people were trying to trick him into eating foods containing sugar. He was excessively involved with food preparation and spent 2 hours rearranging a lunch tray while eating virtually nothing. His food was found in wastebaskets; he expressed astonishment that

this could have happened. Mr. A denied enjoying losing weight, but he was able to date the onset of his weight loss to a period when he became concerned with his appearance and began dieting and exercising, as well as decreasing his alcohol intake. He developed a distorted body image without awareness that his weight loss had become a serious problem. He reported periods of overactivity but denied bulimia or induced vomiting.

Mr. A's food avoidance behavior, distorted body image, and increased activity were suggestive of anorexia nervosa. However, his age, sex, lack of history of an eating disturbance, and successful and independent lifestyle during the preceding 10 years were atypical.

Although the hematologic abnormalities were presumed to be secondary to anorexia, a bone marrow biopsy was performed and revealed lipid-laden histiocytes. Elevation of acid phosphatase, hepatomegaly, and radiographic evidence of osteopenia and cortical thinning of the femur were also noted. Further histochemical studies showed that the foam cells in the marrow contained iron and were PAS (periodic acid-Schiff) positive, which is characteristic of true Gaucher's cells. The diagnosis of Gaucher's disease was firmly established when serum glucocerebrosidase levels were found to be approximately 10% of normal values (3).

Neurological and psychological abnormalities were observed. Neurologic examination revealed definite weakness in the left upper extremity, with questionable abnormalities in the lower extremities. Electromyography (EMG) showed a left radial nerve palsy and mild generalized motor neuropathy in the left upper extremity. The computerized tomographic (CT) scan revealed significant enlargement of the lateral and third ventricles and excessive prominence of the Sylvian fissures and convexity sulci. On the Wechsler Adult Intelligence Scale (WAIS), he obtained a verbal score of 119 and a performance score of 106 with marked subtest scatter.

Mr. A initially resisted a strict, behaviorally oriented high caloric regimen, but with increased cooperation he gained 10.5 kg in 21 days and was discharged with a weight of 50.7 kg. No psychotropic medications were used in Mr. A's treatment; while an inpatient, he was seen daily in supportive psychotherapy.

Discussion

Psychiatric consultation was requested because of the patient's suspected psychogenic weight loss. Multiple symptoms of anorexia nervosa were present, but Mr. A's complaints of weakness, objective evidence of left upper extremity weakness, abnormal findings on EMG, CT scan, and psychological testing, as well as dysarthria pointed to a central nervous system disturbance.

Neil and associates described a family in which the diagnosis of adult-onset Gaucher's disease was followed years later by psychosis and neurologic abnormalities (4). Of the three cases reported, two had generalized weakness and two had large WAIS subtest scatter and verbal-performance differences. One patient had an abnormal CT scan, but all three had abnormal EEGs. Other reports have described adults whose neurological symptoms developed long after the discovery of visceral and bone involvement (5) and weight loss and muscle wasting in the juvenile form of the disease (6).

The argument could be made that Mr. A had two illnesses, anorexia nervosa and coexistent Gaucher's disease. While there is no way to completely rule out this possibility, it is unlikely for at least two reasons. First, the traditional rule of parsimony says it would be most unusual for two such rare diseases to manifest themselves in one individual, especially since a link between adult-onset Gaucher's disease and subsequent psychiatric illness has already been established. Second, the atypical nature of his illness and his rapid improvement with treatment militates against the diagnosis of primary anorexia nervosa.

This case illustrates that adult-onset Gaucher's disease may manifest itself as psychiatric illness. Although it is a rare syndrome, Gaucher's disease should be considered when a behavioral disturbance or psychosis is seen in conjunction with weakness, neurologic abnormalities, or abnormal EEGs or CT scans. While it is unlikely that Gaucher's disease will often manifest itself as anorexia nervosa, it should be recognized as a medical disorder that may appear with psychiatric symptoms.

This case also confirms the need for a rigorous medical workup of patients with atypical presentations of classic psychiatric illnesses. Such situations may actually represent typical presentations of unusual illnesses; awareness of this fact may be a necessary prerequisite in making a difficult or obscure diagnosis.

Acute Hyperkalemia During Lithium Treatment of Manic Illness

BY FREDERICK C. GOGGANS, M.D.

Disturbances of the serum potassium level have not been associated with the use of lithium carbonate in man (1). However, one study (2) showed that there were significant increases in the serum potassium levels of manic-depressive patients during the first 3 months of lithium therapy, even though the increases were within normal physiological limits (3.5–5.0 mEq/liter). The following case report describes a patient who suddenly developed hyperkalemia during the treatment of acute manic illness with lithium.

Case Report

Ms. A, a 67-year-old woman, was admitted to the hospital for the second episode of a psychotic illness. Her symptoms were sleeplessness, hyperactivity, loquaciousness, expansive mood, and paranoid delusions. I diagnosed her as suffering from manic-depressive illness and began a trial of lithium.

Ms. A had no history of medical problems and took no medications before this admission. A physical examination made at the time of her admission revealed no abnormalities. Before lithium was administered, a laboratory evaluation revealed the following: a normal complete blood count; sodium, 142 mEq/liter; potassium, 4.6 mEq/liter; chloride, 102 mEq/liter; bicarbonate, 31 mEq/liter; BUN, 16 mg/100 ml; creatinine, 1.2 mg/100 ml. Her ECG showed a sinus rhythm with a rate of 65 beats/minute; the PR interval was .16; QRS, .08; QT, .36. There was no evidence of any conduction abnormality or previous myocardial infarction. While Ms. A was taking 1200 mg/day of lithium, her serum lithium level was 1.2–1.5 mEq/liter; her manic symptoms decreased markedly on this dose, but her paranoid delusions persisted. During her third week of treatment 10 mg/day of haloperidol were added to her regimen, and her paranoid delusions disappeared.

Haloperidol was discontinued during the fourth week, and she was maintained on 600 mg/day of lithium; her lithium serum levels were 1.0–1.1 mEq/liter. At the end of the fourth week, a routine SMA-6 was as follows: sodium, 138 mEq/liter; potassium, 5.7 mEq/liter; chloride, 109 mEq/liter; bicarbonate, 31 mEq/liter; BUN, 15 mg/100 ml; and creatinine, 1.1 mg/100 ml. Repeat measurements the following morning showed these values: sodium, 136 mEq/liter; potassium, 6.2 mEq/liter; chloride, 103 mEq/liter; bicarbonate, 30 mEq/liter; BUN, 14 mg/100 ml; and creatinine, 1.2 mg/100 ml. This sudden appearance of hyperkalemia was confirmed when a third potassium level, obtained immediately after the morning's results were returned, was 6.2 mEq/liter. An ECG done just before that blood specimen was taken showed sinus bradycardia (55 beats/minute). The PR interval was .16; QRS, .10; and QT, .36. An incomplete right bundle branch block pattern appeared, and the T waves were slightly peaked. Although Ms. A was otherwise asymptomatic for hyperkalemia, she was treated with intravenous glucose, insulin, and oral kayexalate. Lithium was continued. Her serum potassium level fell to 4.4 mEq/liter after 4 hours. Ms. A's serum potassium levels 1, 3, and 7 days later were 4.8 mEq/liter, 4.7 mEq/liter, and 4.8 mEq/liter respectively; the last reading was taken immediately before she was discharged. Her ECG returned to its admission appearance when the potassium level returned to the normal range, and a final tracing on the day of her discharge was also identical to her admission ECG.

Ms. A was discharged and instructed to continue taking 600 mg/day of lithium; her serum lithium level was 1.0 mEq/liter. Three weeks after her discharge, Ms. A's serum potassium level had risen to 5.6 mEq/liter, and her lithium level was 1.0 mEq/liter. Lithium was discontinued and her serum potassium level fell to 4.5 mEq/liter within 1 week. Ms. A's serum potassium level remained in the normal physiological range. Her psychiatric status remained stable for 4 months following her discharge. Then she developed a hypomanic episode, which was treated successfully with haloperidol on an outpatient basis. No cardiac arrhythmias or potassium abnormalities were associated with that episode or its treatment.

Discussion

Ms. A had acute hyperkalemia that was asymptomatic except for the ECG abnormalities described above. These abnormalities were associated with her hyperkalemic state and disappeared following corrective treatment, which suggests that the ECG abnormalities were secondary effects of hyperkalemia. Bradycardia, cardiac conduction abnormalities, and peaked T waves are all commonly associated with hyperkalemia (3).

The differential diagnosis of acute hyperkalemia involves distinguishing pseudohyperkalemia, which is secondary to prolonged tourniquet time or hemolysis before potassium measurement, from true hyperkalemia. This distinction may be made by repeated potassium level determinations or by demonstrations of ECG changes consistent with hyperkalemia. Among the causes of true hyperkalemia are metabolic acidosis, renal insufficiency, Addison's disease, hyporeninemic hypoaldosteronism, periodic hyperkalemic paralysis, drug effect (usually secondary to potassium-sparing diuretics, such as triamterene or spironolac-

tone), excess potassium ingestion, and endogenous release associated with cell injury. However, none of these causes was identified in Ms. A, despite a thorough review of her history with the internal medicine consultation service.

I then considered the possibility that lithium may have caused Ms. A's acute hyperkalemia. With the assistance of the Lithium Information Center at the University of Wisconsin, I made a search of the literature on lithium and hyperkalemia but found no reported case of acute hyperkalemia associated with the clinical use of lithium. Baldessarini and Lipinski reported that ECG changes resembling those of hyperkalemia have been reported in animals. The lithium levels required to induce these changes, however, are extraordinarily high, above 10 mEq/liter, and unlikely to be encountered clinically (4). McKusick also demonstrated in experimental animals that raising the serum lithium level above 10 mEq/liter by intravenous infusion produced a consistent series of ECG changes indistinguishable from those of hyperkalemia (5). He noted that under those conditions lithium caused the elevation of serum potassium levels, probably through direct displacement of the ion from the cell. He concluded that the ECG changes observed were most likely secondary to changes in the ratio of intracellular to extracellular potassium. At levels of lithium used clinically in man, the effect of lithium on ECGs usually resembles those effects associated with hypokalemia. The usual explanation of these abnormal ECG readings has been related to the theory that lithium replaces potassium within the myocardial cell (6). Nevertheless, this replacement has not been associated with changes in the serum level of potassium or with ECG changes resembling hyperkalemia.

Significant increases in serum potassium levels within the normal range have been reported during uncomplicated treatment of manic-depressive illness with lithium. It is not unreasonable to suspect, therefore, that Ms. A's acute hyperkalemia may have been related to lithium therapy. This conclusion is made more tenable by the fact that Ms. A's hyperkalemia returned while she was taking lithium, but it disappeared after lithium was stopped. A possible mechanism for this effect would be that lithium, as it enters the cell, may disturb the electrochemical equilibrium across the cell membrane and increase potassium conductance. A subsequent loss of potassium into the extracellular fluid may lead to hyperkalemia in some patients.

The association of hyperkalemia with the use of lithium at therapeutic levels is particularly important in light of the recent study of Shopsin and associates (7). They reported that there was a 3.8% incidence of sudden death in 105 patients established on maintenance lithium. Their explanation of this unexpectedly high rate of sudden death focused on the hereditary predisposition of the patients who died, but an alternative explanation of these sudden cardiac deaths could be the acute development of hyperkalemia. Further studies seem indicated to detect the prevalence and the effects of hyperkalemia in patients treated with lithium.

Suppression of Plasma Cortisol in Depressed Patients by Acute Intravenous Methadone Infusion

BY PHILIP W. GOLD, M.D., IRL EXTEIN, M.D., DAVID PICKAR, M.D., ROBERT REBAR, M.D., RICHARD ROSS, M.D., PH.D., AND FREDERICK K. GOODWIN, M.D.

A cardinal biochemical finding in major depressive illness is activation of the hypothalamic-pituitary-adrenal (HPA) axis. This activation is manifested both by an overall increase in the daily 24-hour production rate of corticosteroids as well as disruption of the circadian pattern of corticosteroid secretion (1). Most patients with HPA activation also fail to adequately suppress corticosteroid secretion following dexamethasone administration (2).

The etiology of HPA activation in depression is unclear. It has been suggested that this activation is related to altered central biogenic amine neurotransmitter function (3–5). These neurotransmitters have been shown in experimental animals to modulate the secretion of corticotropin-releasing factor (CRF), a hypothalamic peptide that stimulates pituitary adrenocorticotropin (ACTH) release, which in turn stimulates adrenal steroid production (6). It has been demonstrated recently that a variety of neuropeptides may also influence CRF and/or ACTH release and hence corticosteroid secretion. Among these peptides are the endogenous opiates (7), which, like the biogenic amines, have been postulated to play an important role in regulating mood.

To explore the possible interface between endorphinergic and HPA function, we present here a report that, to our knowledge, represents the first study examining the effects of exogenous opiate administration on HPA function in patients with a major depressive disorder.

Method

Four patients who were mildly to moderately depressed and who met the standard Research Diagnostic Criteria (8) for admission to the NIMH clinical research units at the NIH Clinical Center were chosen to receive intravenous methadone. Each patient was drug-free for at least 3 weeks before our study and was given nothing by mouth after midnight the day before infusion of methadone. At 8:00 a.m. a polyethylene catheter was placed in each patient's antecubital vein and 5 baseline samples were drawn every 15 minutes from 9:00 a.m. to 10:00 a.m. At 10:00 a.m. each patient received 5 mg of methadone i.v. in 1 cc of sterile saline given over 1 minute. Additional blood was drawn until 1:00 p.m. at 15, 30, 45, 60, 90, 120, and 180 minutes after the infusion. In accordance with the usual diurnal pattern of cortisol secretion, we sought to control for the expected fall in cortisol levels between 10:00 a.m. and 1:00 p.m. by repeating the procedure on a separate day, except this time placebo (1 cc of sterile saline) was infused instead of methadone. Because methadone has an extended half-life, 5 baseline samples were also drawn in one patient between 9:00 a.m. and 10:00 a.m. the day following methadone infusion to evaluate the possibility of a sustained effect of methadone on cortisol excretion. All plasma samples were assayed for cortisol by radioimmunoassay. Baseline values for each subject were calculated utilizing the average of the 5 samples drawn between 9:00 a.m. and 10:00 a.m. before the infusions.

Results

There was no significant difference in the mean (±SE) of the average baseline levels between the methadone infusion day (102.9±14.3 ng/ml) and the placebo day (92.5±25.1 ng/ml). Methadone induced a progressive decline in cortisol secretion that was maximal at the time the last data point was obtained, 3 hours after the infusion. By this time, cortisol had fallen from the mean average baseline of 102.9±14.3 ng/ml to a mean of 26.0±5.8 ng/ml; this decline represents a mean decline of 76.9±12.1 ng/ml or a mean percentage fall of 73.4±2.8. On the placebo day a progressive decline in cortisol secretion was also maximal 3 hours after infusion. Thus, cortisol fell from a mean average baseline of 92.5±29.1 ng/ml to a mean of 63.8±14.8 ng/ml 3 hours after saline infusion. This decline represented a mean fall of only 28.7±8.7 ng/ml or a mean percentage fall of only 29.7±7.9. The mean percentage fall of cortisol ($p<.01$) and the mean fall of cortisol ($p<.02$) were significantly greater following methadone infusion than they were on the placebo day.

We noted a sustained suppression of cortisol secretion 24 hours after methadone infusion in the patient who was examined for this the following day. The mean baseline cortisol level of this patient was 124.67±28.76 ng/ml, which fell substantially to 39.0

ng/ml 3 hours after infusion and remained suppressed at essentially this level (44.67±2.6 ng/ml) between 8:00 a.m. and 10:00 a.m. the next day.

Discussion

Endogenous opiates interact with HPA function in several important ways. For example, a common precursor prohormone peptide contains the sequence of both ACTH and β-endorphin and is thought to be the source of both peptides (7). Furthermore, in experimental animals, ACTH and β-endorphin are secreted in equimolar amounts concomitantly by a single anterior pituitary cell type and are each regulated identically by specific excitatory, including CRF, and inhibitory stimuli (7). In human subjects, heroin addicts have been reported to show diminished basal ACTH and cortisol levels, which has been interpreted to suggest that opiates, like ACTH, exert negative feedback effects on CRF and/or ACTH secretion (9).

In this study, methadone infusion induced a marked acute suppression of cortisol secretion. This suppression presumably reflects negative feedback effects exerted on CRF and/or ACTH secretion via opiate receptors located at hypothalamic and pituitary levels (10). Other mechanisms for methadone-induced suppression of cortisol secretion are also possible, including direct suppression at the adrenal level, but this possibility seems unlikely, especially in view of the ACTH suppression noted in narcotic addicts.

It has been clearly established that the HPA responds to feedback inhibition by corticosteroids at both hypothalamic and pituitary levels. Compared to normal subjects, depressed patients often show a relatively transient suppression of corticosteroid levels following administration of the synthetic glucocorticoid dexamethasone (2). This response of early "escape" to the standard dexamethasone suppression test implies an elevation in the set-point for feedback inhibition of CRF and/or ACTH in the presence of high circulating corticosteroid activity. If methadone suppresses cortisol levels via feedback inhibition of CRF and/or ACTH, it may be possible to devise a methadone suppression test, analogous to the dexamethasone suppression test, to evaluate the set-point for feedback inhibition exerted by opiates on the HPA.

It should be noted that methadone, like dexamethasone, has an extended half-life, so the extent as well as the duration of HPA suppression following methadone could be meaningfully evaluated. Although the one patient reported here showed no "escape" of cortisol secretion 24 hours after methadone administration, the possibility of early "escape" of cortisol suppression following methadone infusion in more severely depressed patients remains to be evaluated. Thus, it is proposed that the development of a methadone suppression test could be utilized to explore the possible relationship between endogenous opiate function and HPA activation in depressed patients.

Letters must be typed double spaced throughout and should not contain more than 500 words and 5 pertinent references. Criticisms of published articles will automatically be sent to the author(s) for response. Letters will be edited for clarity and conformance with* Journal *style. We regret that we cannot inform writers of the disposition of letters or return those which are not printed.*

From the South African Department of Health

SIR: I am disappointed by the lack of scientific objectivity shown in the Report of the Committee to Visit South Africa (November 1979 issue). South African psychiatrists have respected APA because they believed that it published only objective reports.

The committee was not invited to do, nor did, an in-depth study of the policy of separate development (apartheid) but claimed, "We found that apartheid has a destructive impact on the families, social institutions, and the mental health of black South Africans. We believe that these findings substantiate allegations of social and political abuse of psychiatry in South Africa."

The committee went out of its way to meet opponents of this country's political system and ignored or omitted any positive facts provided by the South African Medical and Dental Council, as well as the South African Nursing Council, who control all medical and nursing practitioners, irrespective of race. There are black elected members on these councils. The 1973 Mental Health Act and the 1977 Health Act apply to all sections of the population without any reference to race. The shortcomings that exist are not merely due to discriminatory legislation or South Africa's policies.

The committee claimed that black patients aged 40–60 years were allowed to die even when a diagnosis of treatable illness like bacterial pneumonia was made. This implies that treatment is withheld from black patients as a result of government policy. The committee did not state that each hospital it inspected had a dispensary and that a full range of medicines was available. Committee members selected files, studied them, and returned them without asking the staff to explain shortcomings in the documentation of a specific deceased patient.

Medical literature does substantiate the observation that psychiatric patients often have lower resistance to diseases than do individuals with better mental health. Since 1934 (Malzberg in New York State) researchers have commented on the high mortality rate among psychotic hospitalized patients. In a preliminary report Hofer and Raymond (1) noticed that the mortality in their psychiatric population, as far as cardiovascular and respiratory diseases were concerned, was of the same ratio as in the general population. Mental illness, however, has an effect on longevity. The mortality rate is modified and death comes at a younger age. Lehmann (2) described how poor communication between patient and staff could cause a patient with schizophrenia to suffer from a serious illness without complaining. A diagnosis may be made in the late stage of the illness, but the patient may still die despite treatment. A select APA committee should have kept these problems in mind.

I dispute the implication that the differences in our service standards result from malicious disregard for other human beings. The Department of Health provides physical facilities to each population group that are usually an improvement on the standard of living of the social environment from which most patients come. The services in these facilities are related to the cultural practices of the group accommodated. World Health Organization guidelines support this practice. The Alma-Alta Declaration on primary health care issued by the WHO in September 1978 supports "essential health care based on practical, scientifically sound and socially acceptable methods and technology made universally accessible to individuals and families in the community through their full participation and at a cost that the community and the country can afford." The committee has confirmed that no unacceptable methods and technology were used in caring for these patients. Committee members visited facilities in the most isolated areas of South Africa. The committee could not find patients who were detained without sound reason, although it did doubt the need to detain certain epileptic patients. However, it is the social aspect of the care that is brought into question. The difference in diet, clothing, and sleeping arrangements and other facilities can be explained by social and cultural differences. Unfortunately, our cultural groups have different skin colors and different levels of social development and therefore critics of our mental health services always refer to politics.

The committee failed to mention the Department of Health's recognition of social development and its policy that all future psychiatric hospitals will be of the same structural standard. The first facility for colored patients implementing this policy will be erected during 1980. Planning commenced in 1975.

Have I failed to convince your readers that shortcomings in a service do not result only from maliciousness or policies? If so, let me cite the following passage from the *New York Times* (3).

> The fetid odor of unclean bodies and the gray-blue haze of cigarette smoke hang like smog about the destitute clientele of the Men's Shelter on the Bowery in Manhattan . . . . Ragged men with vacant eyes sit in the "Big Room" on plastic chairs attached in rows. As many as 250 men will sit all night if there are no beds available in nearby flop houses. Some men will wash themselves . . . but many refuse. Others must be deloused or they cannot stay.

Should South Africans conclude that the democratic, capitalistic, and integrational policies of the United States caused such conditions in New York City? If we accept this direct causal relationship, is not the South African service, provided under the policy of separate development, more humane? Nowhere did the committee find hospital facilities of this standard. The worst of our black patient care is better than this.

Some statements in the report are blatantly incorrect. For instance:

"An extensive response (to the draft report) submitted by the Department of Health in effect denied every critical finding." The Department has not denied a single finding. But the biased and often unsubstantiated conclusions were questioned. The Department of Health offers anyone wishing to verify this a copy of the original reply submitted to APA.

"The Department of Health acknowledged that a patient had been murdered by a nurse." This statement is the result of the following written reply from the Department of Health: "A senior psychiatrically trained (black) male nurse was involved in a struggle after which the patient died. At a trial the nurse was charged with murder but found guilty of culpable homicide."

Dr. Stone, a medical-legal expert of the Harvard University Law Faculty, should know the difference between murder and culpable homicide and that the committee's statement was grossly misleading, if not false. As Chief of Psychiatric Services, I accompanied committee members on probably 80% of their visits, and overheard some of their discussions suggesting that they had found many examples contrary to their preconceived ideas of South African conditions. I reminded them of this. Dr. Stone replied that "some are comments taken out of context, some were made to avoid conflict or confrontation and for reasons of social tact at the time (A.A. Stone: personal communication to Dr. J. de Beer, Secretary for Health, South Africa, Sept. 12, 1979). This is a very significant statement. The committee has again tied "the apartheid tin to the tail of the psychiatric cat" (4).

The committee was elected with a strong political bias. The May 1978 issue of *Bottomline* (5) reported that "Dr. Jeanne Spurlock, Deputy Medical Director [of APA and a member] of the Black Psychiatrists of America was given the assignment of working with other interested persons to determine the names of the people to serve on the committee, and to develop evaluation procedures and instruments."

The "other interested persons" were identified a few paragraphs later—"The Black Psychiatrists of America have joined in an informal coalition with various anti-apartheid groups to call for the freedom and rights for black South Africans."

Bearing in mind that the committee said things for "reasons of social tact" when they were in South Africa, the reader must wonder how much the anti-apartheid political tirade was allowed to influence their report for reasons of social tact in America.

I trust your readers will evaluate the committee's report in the light of the background information I have provided.

DR. P.H. HENNING
Chief of Psychiatric Services
Department of Health
Republic of South Africa
Pretoria

Dr. Spurlock and Associates Reply for the Committee to Visit South Africa

SIR: Dr. Henning was our host in South Africa. He was unfailingly gracious and courteous to our committee throughout our stay. We very much appreciate his many acts of personal kindness to us under circumstances that must have been as difficult for him as they were for us. We hope that his letter and our response will not obscure those sentiments.

Dr. Henning's role as Chief of Psychiatric Services requires him to supervise the facilities we surveyed. His letter therefore must be understood as an official response to a critical report. The APA had given the South African Department of Health and Dr. Henning the opportunity to react to a preliminary draft of its report. We carefully reviewed their detailed critique before preparing our final report. Dr. Henning's letter echoed the substance of the earlier critique: 1) The committee had no mandate and no basis for commenting on apartheid. 2) We gave inadequate attention to positive developments reported by governmental policies. 3) Based on Dr. Henning's understanding of conversations he heard and overheard, the committee distorted the results of its survey. 4) Finally, the letter also contained a new elaboration of the South African response to our findings about the needless death of patients. We will reply to each of these:

1) The invitation from South Africa's Secretary of Health stated that "the prime objective of the visit would be to investigate the accusations of the United Nations Committee against apartheid in regard to psychiatric services in South Africa." The U.N. committee's accusations were made to direct attention to the effects of apartheid. Unequivocal data on apartheid were present in every psychiatric facility and in every community we visited. The impact of apartheid was demonstrated in the discrepancy in appropriations for black, colored, Asian, and white patients. The impact of apartheid was also demonstrated in the difference in the quality of facilities and in the quality of care, which varied directly in relationship to the racial standards established by the government of South Africa.

2. During the 18 days devoted to the survey we were involved in activities jointly planned with South African officials on 16 days. We also independently met with some people who opposed South African policies. We had indicated before going to South Africa that we intended to do this since we did not want to be limited to sources selected by the South African government. We did not find it necessary to go out of our way to meet them. We did what we had planned to do.

3. Dr. Henning indicated, based on his memory of conversations which he quoted out of context, that he was unprepared for the criticisms of the report. He suggested that our report was written by people who are easily influenced by the situation in which they find themselves and that we changed our minds about what we had seen upon returning to America. Committee members met each night in South Africa to tape collective impressions of the institutions we saw and the people we met. Our judgments of these facilities were based on our findings and our group discussions at that time. Dr. Henning was appointed by then President Jack Weinberg to include persons of appropriate expertise. The South African government was informed in advance and agreed to participation of black psychiatrists in this survey.

4. Dr. Henning cited studies that might offer a rationalization for the mortality of psychiatric patients in South Africa. He cited these studies out of context, as he does our conversations with him. Lehmann, for example, specifically refers to crowded conditions and inadequate nursing attention as important considerations in the mortality of schizophrenic patients. Furthermore, the records of the patients who died demonstrated incontrovertible evidence of absent or improper examination, diagnosis, and treatment of treatable illness where death need not have occurred. Charts were chosen at times randomly, at times by hospital personnel, and at times as a block of charts that had been filed together. In the first hospital we visited, with a census of 3,400 patients, we were ushered into a storeroom where there were 375 charts of patients who had died in the previous year. All of these charts were accessible for review, and we chose among them. We paid particular attention to the most recent deaths. Contrary to Dr. Henning's comments, we did ask the staff at some hospitals to explain shortcomings in the reported treatment of a specific deceased patient. We got no further information despite the fact that staff scurried about to find other records. We believe that any objective observer who systematically examined the charts of patients who died in these facilities would confirm our findings. We hope the South African Department of Health will follow the positive recommendations we set out in our report and seek to avoid needless deaths rather than continuing to attempt to deny and rationalize what is happening.

More on the South African Report

SIR: It would not be unreasonable to conclude that the Report of the Committee to Visit South Africa (November 1979 issue) reflected the inequitable distribution of health care to different population sectors in South Africa. The unsatisfactory nature of South African psychiatric and medical services is no less reprehensible because it stems from centuries of sociopolitical conflict between indigenous peoples and settlers. However, critics should understand this history before resorting to knee-jerk assumption.

Many miseries of the human condition may be implicated marginally as deleterious to mental health, including the military occupation of territory by foreigners, as occurs on the left bank of the Jordan River, the hostile 30-year siege of Israel by its neighbors, and the Soviet Union's repressive totalitarianism. The current state of the art of psychiatry does not justify postulating causal connections between these unhappy situations and mental illness. Despite our instinctive revulsion, the offensiveness of the apartheid system alone does not necessarily warrant implicating it as an etiological factor in the genesis of mental illness. The committee's report mentioned no epidemiologic studies of the incidence of mental illness in various South African population groups.

I question the relevance of APA involvement in South African apartheid or in other issues that do not deal with direct perversion of the medical process by failure of a nation's physicians to conform to universally accepted norms of ethical conduct. The committee's survey included no data substantiating charges of that nature.

No society is free of inequity. It must be of meager consolation to an indigent resident of the South Bronx that, while he is not barred by statute from seeking admission to Chestnut Lodge or to Shepherd-Pratt, he is inevitably obliged de facto to seek lesser quality care in a public hospital. The opportunity of society's disadvantaged for equal access to health care in the United States does not substantially differ from opportunities existing in South Africa.

ALEXANDER M. DON, M.D.
Scottsdale, Ariz.

Dr. Stone Replies for the Committee to Visit South Africa

SIR: Dr. Don presented three criticisms of the report. Dr. Pinderhughes responds below to one of these criticisms, and I shall attempt to deal with the others. The strategy of Dr. Don's first criticism was to admit the "unsatisfactory nature" of medical and psychiatric services for nonwhites, to claim that all that is bad is a legacy of the history of South Africa, and to assert that South African physicians have not violated ethical standards. Therefore, the responsibility for what is "reprehensible" lies not with psychiatrists but within the sociopolitical fabric of history which must be understood rather than treated in a "knee-jerk critical" fashion.

I agree with Dr. Don that South Africa's problems are rooted in a history that needs to be understood. So are all human problems. But history, even history understood, cannot become an acceptable excuse for continuing injustices. The Committee to Visit South Africa made a good-faith effort to understand the historical perspective both from a white and a nonwhite perspective. But we also had a duty to make a judgment about the present treatment of nonwhite patients, and we offered suggestions for their better treatment in the future. We suggested feasible remedies for the continuing injustices. Contrary to Dr. Don's reading of the

report, we did find evidence that some physicians violated accepted norms of ethical conduct—they allowed patients to die by withholding routine medical care. There was no knee-jerk response in this. We were at great pains not to condemn all of the "nation's physicians," and we suggested measures to be taken by ethical and responsible physicians and officials in South Africa to monitor and reduce these and other violations of ethical standards.

The second criticism asserted that the disadvantaged in the United States are not substantially better off than those in South Africa. Dr. Don is simply wrong. The United States certainly has not overcome all of its own racial inequities, but by any objective measure nonwhites are substantially worse off in South Africa. The notion, let him who is without sin cast the first stone, is implicit in Dr. Don's criticism. This time-honored maxim surely must be taken seriously, but should it become the justification for a conspiracy of silence among responsible physicians? There can be no question that there has been political abuse of psychiatry and mistreatment of psychiatric patients in various parts of the world, including the United States. This abuse takes various forms and psychiatrists have played different roles ranging from active complicity to passive participation. APA must acknowledge such abuse and speak against it. Otherwise we will fall into a mindless and defensive guild mentality that is amoral. We must remedy our own failings but we must not remain silent until we can speak from a posture of self-righteous perfection. Dr. Don, who is South African-born and trained, may well understand much about South Africa and its history that the committee did not. However, nowhere in his letter did he indicate that he ever visited or evaluated the treatment facilities for nonwhites in his native country and came to different conclusions than did the committee.

ALAN A. STONE, M.D.
Boston, Mass.

Dr. Pinderhughes Replies for the Committee to Visit South Africa

SIR: Dr. Don stated in his letter, "Despite our instinctive revulsion, the offensiveness of the apartheid system alone does not necessarily warrant implicating it as an etiological factor in the genesis of mental illness." The committee believes that frequent and intense life stress is an important etiological agent and precipitating factor for mental and emotional disorders and sometimes for psychosomatic and somatic disorders. In South Africa the committee observed conditions of deprivation, loss, fear, conflict, depression, loss of freedom, discrimination, disruption of family, absence of protection, and frequent encounters with separation, illness, and death. The committee considered these conditions pathogenic, causing great stress to human systems and often depriving these systems of important support. Relationships have been demonstrated between life stress and both mental and physical illnesses and between loss of social support systems and the incidence of mental and physical illness. There is no reason to believe that factors which contribute to morbidity and death in the United States do not do the same in South Africa.

CHARLES A. PINDERHUGHES, M.D.
Bedford, Mass.

Psychotherapy Standards

SIR: I was excited by the attempt of Peter Buckley, M.B., Ch.B., and associates to investigate "Common Mistakes in Psychotherapy" (December 1979 issue). However, the lack of psychotherapy standards makes such an investigation difficult. The authors claimed that "wanting to be liked by the patient" was a mistake. This hypothesis is vague. One school would argue that wanting to be liked by the patient is appropriate and similar to trying to develop a therapeutic alliance with the patient. Others would argue that wanting to be liked by the patient reflects an unresolved developmental conflict in the therapist that must be resolved before therapy can be beneficial. "Wanting to be liked by the patient" must be clarified, then the clarified hypothesis must be scientifically shown to help the outcome of therapy. This would result in a standard for testing the skill of the therapist. Unfortunately, this task has yet to be performed.

The authors considered "premature interpretation" as another mistake. Is an interpretation made in the first session premature? The authors failed to clearly define their criteria. This is also true for "overuse of intellectualization." How did they define intellectualization and what were the criteria for overuse? Much work must be done before we can confidently investigate the area of common mistakes in psychotherapy. I suspect that the authors labeled as mistakes the approaches of the residents that differed from those of the supervisors.

I feel that psychoanalytic psychotherapy is uniquely therapeutic for many situations. Unfortunately, this is still a bias and not a scientifically proven fact. Psychoanalytic hypotheses must be defined in a form that can be scientifically tested. This has not yet been done and is the major weakness in previous attempts to test the validity of psychoanalytic psychotherapy.

BRUCE ROBERTS, M.D.
Chicago, Ill.

Dr. Buckley and Associates Reply

SIR: We share Dr. Roberts' bias that psychoanalytic psychotherapy is uniquely therapeutic for many clinical situations. There is more scientific evidence for this than Dr. Roberts acknowledged. Malan (1) and Luborsky and associates (2) reported evidence favoring the use of dynamic psychotherapy in treating psychosomatic conditions. Research conducted at the Menninger and Tavistock Clinics has provided evidence for the efficacy of psychoanalytic psychotherapy in treating neuroses and character disorders (3, 4).

We agree with Dr. Roberts that psychoanalytic hypotheses must be scientifically tested and that this, along with the issue of patient selection, (i.e., which patients do best with which therapy) remains a central task for contemporary psychotherapy research.

In our study the supervising clinicians who rated the frequency of residents' "mistakes" were all very experienced psychotherapists. We felt that they possessed sufficient clinical experience to judge empirically the beginning therapists' conduct of treatment and what the root causes of badly conducted treatment were. These were individual judgments although the results were grouped for the purpose of data analysis.

We agree that the identification of specific therapeutic factors (including elements of technique) in psychoanalytic psychotherapy is another pressing question for psychotherapy research. We feel that studies similar to that of Strupp and Hadley (5) but with longer treatment courses are urgently needed.

Affective Flattening and Emotional Blunting

SIR: The attempts by Nancy C. Andreasen, M.D., in "Affective Flattening and the Criteria for Schizophrenia" (July 1979 issue) and Richard Abrams, M.D., and Michael A. Taylor, M.D., in "A Rating Scale for Emotional Blunting" February 1978 issue) to discriminate the affective expressions of patients with schizophrenia from those of patients with affective disorders were thought provoking pieces of research. If these major categories of psychosis can eventually be discriminated from one another on the basis of affect, much useful clinical and possibly biological research could follow.

However, at least in Dr. Andreasen's paper, the assumption was made that emotional blunting and affective flattening are synonymous. Hinsie and Campbell (1), in defining disturbances of affectivity, state that "it is probably the incongruity between the affect displayed and the verbal productions of the patient that is more characteristic of schizophrenia than any other change in affect." Nondelusional depressed patients, in my experience, do not reveal this incongruity between the content of their verbal productions and its accompanying affective expression. Their affect expresses the same pessimism, helplessness, and hopelessness that is readily apparent in the content of their speech. This bland congruent affect is best described as flat. (This is true even of many delusionally depressed patients.) Many patients with schizophrenia, on the other hand, do not match their affect with their speech content. Thoughts of murder, fears of possible homosexual assault, or ideas of being controlled by people or machines are often accompanied by a bland, matter-of-fact affect. This bland incongruent affect is best described as blunted. When these same thoughts are accompanied by giggles or smiles, the affect is termed inappropriate.

The work of these psychiatrists is important for a more complete understanding and discrimination of the major psychoses. However, the assumption that emotional blunting and affective flattening are synonymous must be clarified so that future researchers will not become trapped in semantic confusion.

KENNETH R. SILK, M.D.
Ann Arbor, Mich.

Dr. Andreasen Replies

SIR: Dr. Silk is quite right in pointing out that variability in the use of terms to describe psychiatric symptomatology creates a major obstacle to clear communication between clinicians and researchers. Not only do some distinguish between "blunting" and "flattening," but distinctions are often made between "emotion" and "affect." The distinction between flattening and blunting, based on congruence of the affect, is an interesting one, but it is by no means universally accepted. His definition of "incongruent affect" is quite similar to my definition of "inappropriate affect," while his "inappropriate affect" corresponds to what I would call "silly affect," which I see as a subtype of inappropriate affect. For me, the difference between blunting and flattening is quantitative rather than qualitative, with flattening being more severe and blunting less severe. I have no doubt that many other *Journal* readers define these terms quite differently than either Dr. Silk or I do.

Neither of us is necessarily right; it is difficult to develop criteria for determining "rightness" when it comes to defining terms. From the linguist's point of view, the concept of "rightness" does not apply. Words mean whatever the majority of users take them to mean. In science, however, the usual criteria are the reliability of the definition and its clinical usefulness. I hope that eventually, through the use of these criteria and through careful research, a consensus will be reached concerning the meaning of common terms. Although Dr. Silk and I do not agree on our definitions, we certainly do agree that our current semantic confusion should be reduced if not ended.

NANCY C. ANDREASEN, M.D., PH.D.
Iowa City, Iowa

Drs. Abrams and Taylor Reply

SIR: We view emotional blunting as an impairment of emotional life that may be manifested in various aspects of thinking, feeling, and behaving. For this reason we have included among the 16 items of our scale each of the phenomena Dr. Silk describes, without assigning preeminence to any single feature.

We believe that Dr. Andreasen's phrase "affective flattening" is coterminous with "emotional blunting" as we use it, although she specifically limited her rating scale items to directly observable behaviors. We agree with Dr. Andreasen that some depressed patients may show emotional blunting

and that the assessment of this feature in the diagnosis of schizophrenia should be done after excluding patients with diagnosable affective disorder.

RICHARD ABRAMS, M.D.
MICHAEL A. TAYLOR, M.D.
Chicago, Ill.

Minorities and Psychiatric Hospitalization

SIR: In "Ethnic Density and Psychiatric Hospitalization: Hazards of Minority Status" (December 1979 issue) Judith Godwin Rabkin, M.D., raised some important issues about the vulnerability entailed in minority status.

While doing research in Malaysia from 1966 to 1968 I examined the relative rates of hospitalization of Malays and Chinese Malaysians, the two major ethnic groups, in districts where they were relative minorities. Like Dr. Rabkin, I found that when these patients came from a district where they had been in the minority, they were overrepresented in the mental hospitals (1).

Among Dr. Rabkin's plausible explanations for the effect of low ethnic density and psychiatric hospitalization is "decreased support in times of difficulty, such as limited availability of sympathetic understanding, and helpful compatriots." My finding that the readmission rates more strongly reflected the relative minority status for both Malays and Chinese Malaysians than even the overall admission rates did provides evidence for this "support system" hypothesis. As we know from experience in community psychiatry, the presence or absence of a support system, whether psychiatric or interpersonal, is one of the determinants of rehospitalization.

Other explanations of Dr. Rabkin's hypothesis are exposure to others, absence of social buffers, mobility, and feelings of alienation. In another study of Malaysians I found that "fringe" type or transitional communities bear a higher risk for mental (and social) pathology (2). Such communities may be squatter settlements or semiurban villages that attempt to maintain rural traditions and practices while being bombarded by the influences of urban life.

One factor not clearly delineated by Dr. Rabkin is the greater tendency of a minority group to extrude a deviant member as an embarrassment. The majority community might not react that way in regard to one of its members. Dr. Rabkin alluded to this by asking, "Are blacks . . . more likely to be arrested in predominantly black communities and to be hospitalized in white communities?" The difference between arrest and hospitalization is the difference, usually, between externally imposed sanctions in case of arrest and internally imposed extrusion in case of hospitalization.

San Francisco, Calif.

Questioning Nonphysician Examiners in Psychiatric Education

SIR: I have worked in a variety of psychiatric settings—for 9 years in Czechoslovakia under Communist dictatorship, for 2 years in Austria under a democratic government, and for 11 years in the United States. In "Required Educational Objectives in Community Psychiatry" (Feburary 1979 issue) James H. Shore, M.D., and associates wrote that "psychiatric residents will be given a mini-Board examination at the end of their third year of community psychiatry rotation, which will include written examination following the ABPN national Board format and a one-hour oral examination. The oral examination will involve two examiners—a psychiatrist and a nonphysician mental health professional. This will evaluate the trainee's ability to apply his knowledge." Nonphysician professionals should never be allowed to examine or evaluate (and thereby control) a physician in his or her area of expertise. Once such a precedent is established the nonphysician mental health professional may not always be fully qualified. Psychiatry, as a medical subspecialty, could be in this way controlled not only by nonphysician mental health professionals but by others who pretend to be mental health professionals, e.g., religious and political fanatics, or U.S. citizens serving as foreign agents.

In Europe I spoke to psychiatric nursing assistants, *pflegers*, on the territory of the former German Third Reich. From 1939 to 1945, these *pflegers* were ordered to kill "untreatable" psychiatric patients by causing asphyxia through continuous application of ECT. The patient's psychiatrist had to stand by because politicians, "specialists in mental health," gave orders to physicians.

I also worked in Czechoslovakia where psychiatrists had to make false psychiatric diagnoses for political dissidents. Some psychiatrists may have done this in the hope that dissidents might receive more humane treatment in psychiatric hospitals than in labor camps. Nevertheless, nonphysicians gave the orders.

To my knowledge, no one has ever suggested that a surgical resident be examined by a nonphysician professional in surgery. Whether the idea of Dr. Shore and associates is well intended or an attempt to improve the reputation and gain the support of the nonphysician professionals and paraprofessionals in mental health remains unclear. The only situation in which a physician's professional competency and knowledge should be examined by a nonphysician is when the physician is a defendent standing before a judge and jury in a legal and democratic court or when the physician is testifying as a witness.

GEORGE O. KRIZEK, M.D.
Washington, D.C.

Dr. Shore and Associates Reply

SIR: Dr. Krizek criticized our curriculum for psychiatric residents in community psychiatry by focusing on the political implications of nonphysician control by totaljtarian governments of psychiatric treatment. We strongly concur with his concern for this abuse in any country by anyone, physician or nonphysician. However, psychiatric education in this country has a long tradition of interdisciplinary influence, exemplified by the faculty staffing pattern of most depart-

ments of psychiatry with representatives from psychology, nursing, social work, sociology, and anthropology. In many capacities these nonphysician mental health professionals participate in the education and evaluation of psychiatric residents under the authority and supervision of the psychiatry departments. Community psychiatry, in particular, requires physicians' skills in collaborating with other health professions. The participation of these colleagues in the training and evaluation of residents is a valuable educational experience for trainees and faculty alike. We do not delegate the authority for trainee evaluation. Nonphysician mental health professionals participate with us in a collaborative oral examination.

We disagree with the position that community mental health should be directed exclusively by psychiatrists. Note the current distribution of mental health administrators by discipline. At issue here are the unique role and skills of the community psychiatrist in the context of an interdisciplinary work setting. Our curriculum model realistically addressed that issue without diffusing the physician's role in community mental health. No psychiatrist should abuse his or her special responsibility, whether directed to do so by a physician or a nonphysician supervisor.

JAMES H. SHORE, M.D.
J. DAVID KINZIE, M.D.
JOSEPH D. BLOOM, M.D.
Portland, Ore.

Recognizing Geriatric Sexuality

SIR: The medical, nursing, and allied professional staff of any geriatric home or institution would agree that their objectives are to meet the physical, psychosocial, and spiritual needs of the residents. In regard to physical needs, I question the adequacy of provisions made for the sexual needs of the residents.

A prime prerequisite for the sexual experience is privacy. Residents' rooms, in practice, are not locked; most do not have locks, allowing the entrance of personnel at any time. It is difficult for residents to find the privacy they may desire to satisfy their own sexual needs.

The normalcy of the continued sexual drives of residents in their seventh, eighth, and even ninth decades should be stressed to all personnel. Staff members should regard a male resident who continues to read *Playboy* or an 86-year-old woman who is found crying because she is lonely for a mate as seriously as they would regard younger patients.

As health care professionals, we must recognize that sex, as a pleasure, a physical body function, and a need should not be denied an individual on the basis of age. It is incumbent upon us to teach others, including family members, accordingly.

MARTHA M. WILLIS, R.N.
Montreal, Que., Canada

Dermatosis and Lithium Therapy

SIR: We noted with interest the clinical report entitled, "Lithium Carbonate and Psoriasis," by Dwight L. Evans, M.D., and Willis Martin, M.D. (October 1979 issue). We wish to report another case of a dermatological complication with lithium carbonate use.

Ms. A, a 22-year-old woman with a 5-year history of bipolar affective illness, was treated with lithium carbonate. She had had no previous dermatological condition and no family history of any skin disorder. She had not previously taken lithium. Her serum lithium levels, determined biweekly, ranged from 0.55 mEq/liter to 0.65 mEq/liter. During the second week of lithium therapy Ms. A developed an acneiform rash in the perioral area that spread to both of her cheeks and later to her forehead. Cheilosis was observed at the corners of her mouth. Her condition gradually worsened over several weeks. She was referred to a dermatologist, who prescribed systemic antibiotics—tetracycline and then minocycline. In addition, he prescribed a topical compound of lincomycin and hydrocortisone in a Cetaphil lotion base. After 2½ weeks of this therapy Ms. A's condition had not improved. A gradual decrease in lithium dosage produced slight improvement. However, it was not until lithium had been discontinued for 3 weeks that Ms. A's dermatosis disappeared completely.

Ms. A's condition seems to resemble cases previously reported by Kusumi (1). We hope this report will generate further interest in the possible causal association between lithium carbonate and dermatological conditions.

WILLIAM R. LEVINE, M.D.
Wichita, Kans.

Psychopharmacologic Norms in Blacks and Whites

SIR: "A Pilot Study of Racial Differences in Erythrocyte Lithium Transport" by Samuel Okpaku, M.D., Ph.D., and associates (January 1980 issue) was a laudable departure from reports that are spin-offs from studies primarily aimed at other questions. The fact that previous observations of such differences have been incidental findings may have contributed to the failure of researchers to follow up their preliminary results.

More than ten years ago Overall and associates studied response patterns to antianxiety, antidepressant, and antipsychotic medications in a collaborative effort involving 372 patients in 5 Veterans Administration hospitals. They found statistically significant differences between the responses of blacks and whites, independent of social class disparities, and concluded that "race is an important additional source of difference in drug response that should be taken into account in future research" (1). Henry and associates reported similar findings in their investigation of 240 patients who had received antianxiety and antidepressant agents (2). Raskin and Crook studied 555 white and 159 black depressed patients in a multihospital study (1 state hospital, 2 private institutions, and 2 general hospitals). Black patients had a better response to medications, especially early in treatment (3). In Ziegler and Biggs' study (4) black subjects exhibited a higher mean plasma level of nortriptyline than white subjects did. Ziegler and Biggs observed that this may explain racial

difference in clinical response. Differences in lithium erythrocyte transport may have similar clinical consequences. For example, optimal plasma lithium levels for the treatment of mania are much lower in Japanese patients than in American patients (5).

Major racial differences in the action and efficacy of psychotropic medications would probably have been evident in clinical practice. But the above examples do raise the possibility of subtle variations in efficacy, steady-state plasma levels, therapeutic windows, and toxicologic norms that may act as compounding factors in research based on racially mixed groups of patients. Such subtle variations may also be important in the management of individual patients. Thus the information that depressed black women respond better to chlorpromazine than to imipramine, while the reverse is true of depressed black men (3), may be valuable in "resistant" cases.

Further research seems indicated. While prospective studies are ideal, retrospective analyses of completed investigations are also useful and have the added advantage of avoiding the Hawthorne effect, in which the act of observation significantly affects the perception of dependent measures.

Corrections

There was an error in "Toward a Rational Pharmacotherapy of Depression," by Stephen L. Stern, M.D., A. John Rush, M.D., and J. Mendels, M.D., in the May 1980 issue. The last full sentence on page 547 should read, "For example, Glassman and associates (47) reported antidepressant response to imipramine in 13 of 14 patients. . . ." The staff regrets this error.

On page 447 of the April 1980 issue, in "Unmasking Masked Depression in Children and Adolescents," by Gabrielle A. Carlson, M.D., and Dennis P. Cantwell, M.D., the data in table 3 are incorrect. The correct table appears below.

TABLE 3
Depressive Symptoms in 61 Children Grouped According to *DSM-III* Diagnosis

BOOK REVIEWS

NANCY C. ANDREASEN, M.D., BOOK REVIEW EDITOR

Out in Inner Space: A Psychoanalyst Explores the New Therapies, *by Dr. Stephen A. Appelbaum. Garden City, N.Y., Anchor Press/Doubleday, 1979, 510 pp., $14.95.*

In the spirit of the Zen koan one definition of enlightenment goes like this: before enlightenment one looks at a tree and sees the tree, and after enlightenment one looks at a tree and sees the tree. Before Appelbaum began his odyssey he was a psychoanalyst with an unusually open and inquiring mind, and after six years of wandering the trails and byways of humanist psychology, the consciousness movement, and holistic medicine, he was a psychoanalyst with an unusually open and inquiring mind. But he wasn't the same man.

Out in Inner Space is a companion piece to Adam Smith's *Powers of Mind* (1) (reviewed in this journal in June 1977) in that both authors are mature and sophisticated observers with sound, well-developed points of view who ventured into a psychological netherworld so near and yet so far from the disparate activities that define the American psychiatric establishment. Both authors immersed themselves—literally and figuratively—in the waters of their subject matter. Appelbaum participated in "trial by fire" in the following "outer" therapies and concerns (some farther "out" than others): Esalen workshops, acupuncture, Gestalt groups, psychic healing exercises, shiatsu massage. Kirlian photography, biofeedback, Rolfing (all 10 sessions), post-Rolf structural patterning, the Alexander technique exercises, bioenergetics therapy, est, Silva mind control, and several different kinds of meditation. He even spent 14 months on a macrobiotic diet.

Appelbaum discusses the techniques and strategies he encountered and the underlying theory of each, when there was one, in terms of psychoanalytic theory. Here the book occasionally lags, although the effort is honest and pioneering. It is not inappropriate that Appelbaum discusses psychoanalysis in the context of "outer" therapies and attempts also to defend it from its critics, but often it appears that he takes the criticism more seriously than the critics. Humanistic psychology is not yet much committed to debates on theory; for the most part it is a universe where what counts is what works. To a surprising and challenging extent, many "out" things do work, and we who are "in" have no better frames for understanding those results than labels like transference cure, suggestion, and flight into health. It is useful to remind ourselves that the main use of psychoanalytic theory is to deal with data drawn from the analytic consulting room. Applications to nonclinical or atypical clinical situations are tricky at best. On the other hand, it is surely fascinating when Appelbaum compares the methods of psychoanalysis with those of yogic meditation and finds far more homologues than anyone could expect to find by sheer coincidence. Some deep undercurrents of connection must exist between the two, but what are they?

Like *Powers of Mind, Out in Inner Space* is more a travelogue than a scientific treatise. It is a thoughtful account of a return from nearby strange, mysterious, and evocative places. It is also an invitation. One cannot come away from the book without being intrigued and challenged. There is simply too much of obvious relevance to modern psychiatry and medicine to ignore; yet, in large measure, it is ignored. The paradox that challenged Appelbaum more than any he encountered on his journey was an attitude he confronted in a respected psychiatrist who was working with cancer patients. This man not only knew virtually nothing of the meditative therapy developed by Dr. O. Carl and Stephanie Simonton, he was resistant to hearing anything about it. To quote Appelbaum, here was "a celebrated authority [in cancer], recipient of thousands of government grant dollars, functioning in one of the country's major medical centers . . . content, if not complacent, at overlooking the possibilities for curing cancer, despite evidence from his own patients" (p. 370). On January 1, 1978, 45% of all of Simonton's cancer patients were alive more than twice as long as the national average for survival after the first diagnosis of cancer; this figure is made more impressive by the notation that every Simonton patient was judged medically incurable before coming to the Simontons. Appelbaum is obviously compelled by what he saw and learned in the outer space of psychic healing. He remains at work on research in this field and has a manuscript on that topic in preparation.

Appelbaum and Smith are of a small group of objective observers who have traveled in "outer space" and returned to us with the same message: it doesn't all make sense in the paradigm of our rational Western scientific world, but "something" is out there. It seems inevitable that that "something" will be studied and that the future of our psychological sciences will be shaped thereby. *Out in Inner Space* is a fine launching pad.

JUSTIN SIMON, M.D.
Berkeley, Calif.

Psychiatry for Lawyers, revised ed., *by Andrew S. Watson, M.D. New York, N.Y., International Universities Press, 1978, 451 pp., $25.00.*

"The knowne certaintie of the law, is the safetie of all," wrote the venerable Sir Edward Coke. Dr. Andrew Watson, perhaps the dean of law and psychiatry in this country, is more than a little suspicious that, in their search for a secure certainty, lawyers (and law students, whom Dr. Watson is a master at educating) may miss the enthralling ambiguities of client behavior that make law practice so rewarding for those sensitive to them. His revised edition of *Psychiatry for Lawyers* is a lucid and graceful attempt to open up new vistas for us lawyers, who are probably characterologically predisposed to be better talkers than listeners. Dr. Watson

teaches us to watch and to listen, not only to our clients but to ourselves.

He educates us in the use of transference and countertransference, through examples that the lawyer can readily understand: the young attorney, just started at work with a large law firm, who has difficulties with his superior because he unconsciously confuses him with his dogmatic father and is therefore afraid to show the necessary initiative and independence, the young woman client who tearfully seeks a divorce that, as further investigation reveals, is more on her parents' agenda than her own. In a discursive style, which is the pattern of the book, Dr. Watson instructs us in the development and growth of the personality and about the ego and its defenses and takes us gently through stages from orality to senescence. This is not a "how to do it" book, a short primer for lawyers. It is a book to be chewed and digested. If the readers' experiences are anything like my own, they will recognize some part of themselves on every page, not always with comfort but assuredly with profit. Indeed, I fear that the title of the book may unduly restrict is circulation. It is the best general introduction to normal personality development for the layman that I have yet encountered. Friends to whom I have lent it have retained it for an unusually long time, so fascinating a mirror is it on themselves and their relationships. Perhaps Dr. Watson could be persuaded to bring this out in another edition as well, with much of the legal material excised. It should be titled *Psychiatry for Everyman*.

In not being a "how to do it" book, it is the ultimate "how to do it" book because it emphasizes that a glimpse into the workings of the human mind comes only after deep and quiet pondering. This book should be read anew each time one encounters a client with a complex human problem. *Psychiatry for Lawyers* is so rich a book that new realizations and nuances will glint out from each page, making the lawyer more sensitive to his or her own role and the situation before him. One of the great virtues of this book is the sets of problems and questions that are posed after each chapter, which give the more theoretical material preceding it a local habitation and a name. We encounter "The Case of the Murder for Magic," in which a Spanish-speaking farm laborer has signed a confession stating that he buried his victim under the floor of a chicken coop and later dug up the body, decapitated it, neatly cleaned the skull, and performed a voodoo ritual. We encounter a troubled adolescent—a "nice boy" who has been given "everything he wanted"—whose mother cannot comprehend why he was arrested for thievery while at college. Dr. Watson makes the at first inexplicable much more understandable, given a person's internal history and culture, and shows how a jury can honestly be brought to the same compassionate understanding.

Dr. Watson's range of knowledge and allusion help him convey the insights of his profession. A *New Yorker* cartoon, for example, makes vivid a very destructive closeness between mother and son. He also illustrates his ideas with references to *Cat on a Hot Tin Roof, Tea and Sympathy*, President Carter's *Playboy* interview, *The Diary of Anne Frank*, and ancient Egyptian philology, among others.

What is most impressive about Dr. Watson is his honesty and lack of pretense. A final chapter on the preparation of psychiatric expert testimony for the courtroom is the chief addition to the first edition. It is clear that Dr. Watson wants to play no games. He does not want his experts to befuddle a jury with descriptive labels but to lay out clearly, after thorough preparation, the etiology of a defendant's illness or condition, how the defendant came to be the human being who exploded in a certain way. Nor should the psychiatrist be coached overmuch by the defense lawyer: to do so would detract from the naturalness of his or her presentation. He is skeptical about psychiatry's capacity to predict behavior, despite the demands of many in the legal system for such an opinion. To eliminate controversy, he suggests that expert witnesses for both the prosecution and the defense examine the defendant simultaneously. He also thinks that the defendant should not decline to take the stand. Finally, Dr. Watson is very clear regarding what psychiatric testimony is about. It is to try to explain behavior, not to make moral judgments, "for psychiatrists are no more competent to make moral judgments than other members of society." Radical recommendations, perhaps, in this age of trial tactics, but such common sense.

MAURICE DEG. FORD, J.D.
Cambridge, Mass.

The Psychopath in Society, *by Robert J. Smith. New York, N.Y., Academic Press, 1978, 157 pp., $12.00.*

The author writes that theorists and diagnosticians have presented a wide variety of viewpoints on the etiology of the psychopath: genetic, developmental, psychologic, and sociologic. To these perspectives he adds another, that the psychopath can be conceived more appropriately as the logical extension, or perhaps the fantastic exaggeration, of what Western societies demand for a person to gain individual fame and fortune.

In developing his thesis Smith leans heavily on a concept of Machiavellianism formulated by Christie in 1964. He states that Machiavellianism has four characteristics:

> 1) A relative lack of affect in interpersonal relationships—manipulating should be enhanced by viewing others as objects. 2) A lack of concern with conventional morality—regarding lying, cheating, and deceit in general, manipulators should have a utilitarian view of interaction with others. 3) A lack of gross psychopathology—the manipulator is hypothesized to take a rational view of others and is in contact with objective reality. 4) Low ideological commitment—he is more interested in tactics to an end rather than inflexible striving for the idealistic goal.

A "Mach Scale" of 20 items was constructed to identify people with Machiavellian characteristics. The scale included such items as, "The best way to handle people is to tell them what they want to hear" and "Honesty is the best policy in all cases." The "Machiavel" would agree with the first and disagree with the second. This scale has been used in studies to discover personality correlates of the Machiavel. People who receive high Mach scores are manipulative, judge others as untrustworthy, do not concern themselves altruistically, and less readily enter into relationships to produce mutual solutions to problems. The individual with a high Mach score is also relatively unmoved by others and seems equally unaffected by his or her own beliefs and even

his own behavior, can successfully argue a position different from his own, is rated as less anxious by judges, and can look an accuser in the eye steadily while denying cheating. These traits are called the "cool syndrome." They share commonalities with the portrait of the psychopath painted by the theorists: manipulative, self-oriented, convincing, and distrustful.

Smith says that "the social philosophy basic to a given culture colors the process of diagnosing psychological problems." The American personality has undergone a change from the "Protestant ethic," with its emphasis on hard work, frugality, and prudence, to a new "social ethic," concerned with enjoyment and consumption and obsessed with selling and buying. A philosophy of the marketplace prevails in which selling one's personality promotes achievement.

The achieving personality is described as adventurous, self-confident, assertive, restless, ambitious, self-centered, shrewd, competitive, and individualistic. Superlatives are used to extol this personality as a superstar who has an obsession with display and bigness. The culture applauds and reinforces behavior that earns the label "psychopath."

> If the . . . culture requires projecting a good image while watching out for oneself, if it encourages pursuit of material pleasure and the merchandizing of people, then far from being a mask of sanity or a moral imbecile, the psychopath is the reasonable one and those of us who are trusting, reliable, and empathic are out of phase with reality.

This is an interesting point of view in a well-written book. I recommend it be read by all who are concerned with the psychopath.

PAUL E. HUSTON, M.D.
Iowa City, Iowa

Clinical Pharmacology of Psychotherapeutic Drugs, *by Leo E. Hollister, M.D. New York, N.Y., Churchill Livingston, 1978, 226 pp., $19.50.*

Over the past four to five years a plethora of monographs in the field of psychopharmacology has appeared. With the proliferation of so many books in this field, I wonder where the value of yet another monograph lies. *Clinical Pharmacology of Psychotherapeutic Drugs*, however, is truly a unique book. Perhaps its major strength lies in Dr. Hollister's ability to convey the knowledge of a man who has devoted over a quarter of a century of his professional life as a teacher, clinician, and researcher to clinical psychopharmacology. Dr. Hollister's ability to integrate these three areas of endeavor and to interweave the pharmacologic principles of psychotropic drugs in the context of treating the patient has resulted in a monograph that is clear, concise, and filled with factual information.

Chapter 1 is an overview of Dr. Hollister's approach to the use of psychotherapeutic drugs in the treatment of emotional illness. Although this is not a major philosophical treatise, Dr. Hollister discusses his approach to treatment, which includes recognition of mental illness, the utility of drug treatment, the benefits to be derived and the risks to be weighed when using psychotherapeutic drugs, and a conceptualization of the "ideal drug."

Chapter 2, "Antianxiety Drugs," begins with a brief discussion of the nature of anxiety, the chemical classes of anxiolytic drugs, pharmacologic action of specific drugs, pharmacokinetics, and metabolism, followed by a discussion of the clinical uses of these compounds with emphasis on dosage, therapeutic and side effects, and the general use of the antianxiety drugs. The section on pharmacokinetics and metabolism is extremely helpful in understanding the action of the benzodiazepine drugs and those characteristics which distinguish benzodiazepine drugs from one another. As an example, intramuscular diazepam and chlordiazepoxide are absorbed erratically due to the vehicle used in the manufacture of both these drugs. Thus, in a clinical situation where diazepam or chlordiazepoxide is to be used, the preferred route of administration would be orally, or intravenously if the parenteral route of administration is desired.

The section on Clinical Use of Anxiolytic Drugs is rich with practical suggestions for the clinician treating the patient for whom an anxiolytic drug would be prescribed. Dosage schedules, drug combination, duration of treatment, interactions, and side effects are some of the areas discussed. This format is basically carried out in each of the four subsequent chapters, "Hypnotic Drugs," "Antidepressant Drugs," "Antipsychotic Drugs," and "Lithium and Manic-Depressive Disorder." In each of the chapters Dr. Hollister carefully develops pharmacologic and pharmacokinetic principles, discussing plasma drug levels, metabolism, and kinetics, intertwining these principles into treatment concepts.

The understanding of the clinical use of antidepressant drugs is made clearer by inclusion of a discussion of metabolism, pharmacokinetics, and plasma levels. The practical considerations in the prescribing of tricyclics or monoamine oxidase (MAO) inhibitors in the treatment of depression is presented in such a fashion that the reader gains a full understanding of these drugs in respect to dosage, spectrum of activity, and side effects.

To review each of the remaining chapters would be redundant. Each chapter follows the format described above so that the reader can logically follow each chapter in the monograph and make comparisons between classes of drugs with relative ease.

In summary, *Clinical Pharmacology of Psychotherapeutic Drugs* is a concise, clear, erudite book. This monograph provides technical and clinical information and would be a valuable asset to medical students in their clerkship in psychiatry and clinical pharmacology, to the resident in psychiatry as well as any specialty where psychotropic drugs are used, and to the seasoned clinician and/or researcher.

BURTON J. GOLDSTEIN, M.D.
Miami, Fla.

Current Developments in Psychopharmacology, Vol. 5, *edited by W.B. Essman and L. Valzelli. New York, N.Y., SP Medical & Scientific Books (Spectrum Publications), 1979, 465 pp., $50.00.*

This volume consists of 10 invited papers representing important current developments in the field of neuropsychopharmacology. The search for a "language" to facilitate communication between basic scientists and clinicians is the leading theme of the book. Andreoli and Maffei review methods in collecting clinical data that meaningfully communicate.

to basic research, and Valzelli discusses some of the neurochemical contributions that have opened the possibility of communication between biochemical concepts and behavior.

Recognition that putative neurotransmitters may have a role in the regulation of normal and pathological behavior has stimulated research to explore whether substances such as histamine fulfill the criteria of neurotransmitters (the chapter by Schwartz and associates) and to develop techniques such as *d*-amphetamine-induced hypothermia that could render the effects of pharmacological agents on specific neurotransmitter functions accessible to investigation (the chapter by Yehuda). Shore discusses the effect of stress on neurotransmitter kinetics, with consideration of biochemical genetics, in relationship to the psychobiology of schizophrenia, and Burns and Mendels review the possible role of the neurotransmitter serotonin in affective disorders. In describing circadian rhythms in manic-melancholic disorders, however, Mellerup and Rafaelsen hypothesize that very rapid changes in mood indicate derangements of distribution rather than derangements of production of neurotransmitters, neurohormones, or other critical factors.

There is also a paper by Malick on the pharmacology of isolation-induced aggressive behavior and by Brain and Bowden on sex-steroid control of fighting in male mice. Rigter and Van Riezen review current developments in regard to the effect of neuropeptides in amnesia with special emphasis on the possibility that ACTH analogues may facilitate the retrieval process and vasopressin analogues may facilitate both memory consolidation and retrieval.

The authors included in this volume are prominent scientists and clinicians; their contributions are of high quality. The editors have done a commendable job in identifying topics that are of importance. However, it should be recognized that each paper in this volume is written for a different audience.

THOMAS A. BAN, M.D.
Nashville, Tenn.

Progress in Psychobiology and Physiological Psychology, Vol. 8, *edited by James M. Sprague and Alan N. Epstein. New York, N.Y., Academic Press, 1979, 334 pp., $35.00.*

This monograph might be considered of greatest interest to the neurophysiologist, to the behaviorist, to the neurologist, and, finally, to the psychiatrist, in that order. The topics covered in the seven chapters range from somewhat exotic areas of neuroanatomy to a variety of animal behavior experiments involving regulation of such basic functions as sleep, wakefulness, stress, appetite, suckling behavior, and mother-young relations. In all instances the chapter authors are well versed in their topic and write with commendable clarity and generality. Fortunately, the volume is not at all rendered obscure by the use of specialized terminologies.

The first chapter reviews the neuroanatomic and physiologic relationships of cortex and subcortex and presents some new ideas that would be of considerable interest to the anatomist and neurophysiologist. The second chapter reviews recovery mechanisms that are manifested following lesions of the visual cortex in the monkey. This is followed by a rather specialized chapter on neurophysiologic mechanisms operative during sleep that particularly emphasizes "PGO waves" and their occurrence in REM sleep. This is meant for the specialist.

Although the first three chapters could be interesting to neurologists, their psychiatric application must be regarded as minimal. However, the fourth chapter has to do with stress and arousal and reviews a psychoendocrine hypothesis to account for these phenomena. This chapter will be of considerable interest to both specialists in the field and those psychiatrists who wish some guidance and stimulation from basic research. The next chapter, on postprandial satiety, reviews mechanisms of appetite, surely of interest to those who treat the obese and who are concerned with burgeoning problems of fitness and overweight. Finally, there are two chapters that provide some basic information on the development of suckling behavior. Specifically, the last chapter concerns the interrelationships of mothers and their young.

In summary, the average psychiatrist will not find very much of interest or importance in this volume. However, for those with an academic inclination or those who have to present lectures on the more basic aspects of psychologic function there is some very significant and well digested information. Material in some of the later chapters would also form an excellent background for discussion of clinical syndromes with an organic or neuroendocrine bent, and the inclusion of such information would often add some interest and excitement to an exposition of what might be an otherwise rather humdrum clinical case.

REGINALD G. BICKFORD, M.B.B.CHIR.
La Jolla, Calif.

Research in the Psychobiology of Human Behavior, *edited by Eugene Meyer III and Joseph V. Brady. Baltimore, Md., Johns Hopkins University Press, 1979, 136 pp., $14.00.*

The seven papers that comprise this volume were presented as part of the Adolf Meyer Symposium on Psychobiology in 1976, organized to mark the centennial of the Johns Hopkins University and to honor the first chairman of the Henry Phipps Psychiatric Clinic and originator of the term "psychobiology." The editor's preface describes the great influence Adolf Meyer had on the practice of psychiatry in this country.

The text is a wide-ranging collection of reviews of the contributors' work in an area that can be broadly defined as psychobiology. For the most part, this work has been described elsewhere in greater detail and is now dated by three to four years. Nonetheless, if some of the chapter descriptions below sound unfamiliar and interesting, the reader might judge the book a worthwhile purchase.

Floyd Bloom starts with a description of some of his work on norepinephrine synapses in the brain, particularly those projecting from the locus coeruleus to cerebellar Purkinje cells and hippocampal pyramidal cells. He discusses electrophysiological, histochemical, biochemical, and behavioral evidence suggesting that the locus coeruleus may function as a system for attributing value to environmental signals and relates possible malfunction to perceptual inundation in schizophrenia. This section especially suffers from being dated by several years because there is no mention of newer pharmacological data such as the role of opiates in locus coeruleus function (1, 2). He concludes with a brief allusion to possible animal lesion models of depression.

Seymour Kety continues with his well-known work on the genetics of schizophrenia, using adoption records in Denmark. After a brief discussion of earlier twin studies (which found a concordance rate of about 40%–60% in monozygotic twins versus about 10% in dizygotic twins) and their limitations, he gives a fairly complete description of his own multifaceted studies of adoptive versus biological relatives of schizophrenic index cases. As shown in detailed tables, the overall incidence of schizophrenic illness in biological relatives was about 14% compared with about 3% in adoptive relatives. Kety eliminates possible uterine and early mothering influences by demonstrating an increased incidence of schizophrenic illness in paternal half-siblings of index cases compared with controls.

Edward Sachar discusses three approaches in the field of psychoneuroendocrinology: 1) studies of the effects of psychological stress on endocrine function and the benefits of being able to cope, 2) analysis of neuroendocrine regulation as a window on hypothalamic function in psychotic states, with emphasis on the hypersecretion of ACTH in depressive illness and the normal inhibitory effects of norepinephrine on ACTH, and 3) the use of hormonal responses to illuminate psychoactive drug effects, with emphasis on dopamine's inhibition of prolactin secretion and the effects of neuroleptics. The major exception to the correlations that are described in the last section was clozapine, which produced little or no extra prolactin secretion in spite of being an antischizophrenic drug.

Neal Miller's chapter, titled "Psychosomatic Effects of Learning," starts with a discussion of the accelerating pace of change, the stresses it generates, and their possible effects. He continues with experimental studies in rats demonstrating the beneficial effects of being able to anticipate or avoid shocks in terms of reducing stomach lesions, reducing corticosteroid levels, or elevating brain norepinephrine levels. In some experiments, pargyline or habituation to stress or to tetrabenazine appeared to protect rats from behavioral disruption produced by subsequent exposure to the stress of severe, unpredictable, inescapable electric shocks. After briefly considering the effects of stress on the cardiovascular and immune systems, Miller ends with a discussion of the conditioning of visceral responses and the use of biofeedback in combatting postural hypotension in paraplegic subjects.

John and Beatrice Lacey, in a somewhat difficult to follow chapter titled "Somatopsychic Effects of Interoception," present evidence in favor of their theory that baroreceptor discharge is inhibitory to sensorimotor activity and is facilatory to internalized cognitive abilities. The major evidence was the demonstration of time variation within the cardiac cycle of motor responses that gated further sensory input.

Martin Roth briefly describes his scheme for classifying affective disorders, emphasizing the importance of classification in spite of its neglect by Meyer and emphasizing the true heterogeneity of the conditions discussed. Although he states that the utility of classification comes from the ability to predict response to different forms of therapy, he makes no attempt to incorporate possible biochemical differences among patients into the classification.

The concluding chapter by Gerald Klerman considers the legacy of Adolf Meyer and how the Meyerian pluralistic approach and emphasis on early environment should be modified to incorporate greater use of statistics and adequate controls.

Crazy Talk: A Study of the Discourse of Schizophrenic Speakers, *by Sherry Rochester and J.R. Martin. New York, N.Y., Plenum Press, 1979, 221 pp., $25.00.*

This experimental study of the discourse of schizophrenic speakers is a landmark in the interdisciplinary approach to cognition and language. At best, talk about talk introduces complexities that call for the use of a metalanguage. Talk about "crazy" talk adds a psychological dimension. The authors resolve this requirement with the high-powered lense of psycholinguistics, focused precisely on the particularities and operations of language that mediate coherence and meaning.

Crazy Talk introduces the notion of discourse failures that "occur when the listener cannot follow the speaker, even though the speaker is using familiar words in generally well-formed sentences." Talk familiar to the clinician as schizophrenic is illustrative of discourse failure. To approximate natural language use, the authors select context material extended in time and spread over a range of situations: the unstructured interview, narrative, and cartoon interpretation. The speakers were three groups of 10 subjects each: 10 normal voluntary subjects and 20 schizophrenic patients subdivided in accordance with an index of formal signs of thought disorder.

The study achieves a verifiable documentation of linguistic operations involved in the aberrant talk of schizophrenic speakers and, further, demonstrates significant differences in these operations correlated with subjects with and without thought disorders. The two principal linguistic methods introduced as exploratory instruments are cohesion analysis and the network system of reference and retrieval categories.

The procedural and experimental part of the analysis, which constitutes a major segment of this book, is presented in detail and accompanied by careful critique and evaluation. A very rewarding feature of this study is the evaluation of assumptions and hypotheses that have guided theoretical and experimental approaches to schizophrenic thought and language. This leads to a survey of the pertinent linguistic methodology of recent decades. In the theoretical justification for their experimental design, the authors provide an instructive exposition of linguistic concepts and methods.

The concluding section places the interpretation of findings within the original objective. With this as a point of departure, the authors engage the reader in a challenging consideration of theoretical implications and hypotheses; for example, language versus thought as the essential problem in thought disorder, evidence of lateralized dysfunction in schizophrenia, and thought disorder and diagnosis of schizophrenia.

This study provides a model for the transformation of impressionistic and intuitively perceived "crazy talk" into a

systematized, reasoned, verifiable, and predictable assessment of deviations in discourse.

MARIA LORENZ, M.D.
Belmont, Mass.

Dual-Career Marriage: Conflict and Treatment, *by David G. Rice, Ph.D. New York, N.Y., Free Press (Macmillan Publishing Co.), 1979, 185 pp., $12.95.*

Dr. Rice has written a lucid book that provides psychological understanding and clinical approaches in an area of our rapidly changing psychosocial system: marriages in which both husband and wife have a career. The strength of the book lies in its solid clinical base, frequently illustrated by process notes from couple therapy sessions from Dr. Rice's practice.

The book is rich with thoughtful assessments of the personality traits of spouses that suggest either a good or a bad prognosis for the marriage. As an example, the troublesome dynamics of vulnerability to an injury to self-esteem due to frustration of dependency needs suggest a bad prognosis. From his complex clinical data Dr. Rice abstracts three dynamic issues that carry the greatest emotional charge in dual-career marriages: 1) competition for power, 2) frustrated dependency needs, and 3) lack of adequate support and appreciation.

He details the problem of a dearth of successful models for dual-career marriages. Marriage that begins with only the husband working is studied with particular attention to the need for techniques of working out a new marital contract (analogous to the findings of Visher and Visher [1] with regard to "blended" families).

The author shows a special sensitivity to the different issues that face married career women: the need to integrate the roles of career person, spouse, and, often, mother. Dr. Rice documents the career woman's need for a role model, especially in a close woman relative or friend.

There are many useful technical suggestions in the chapters on marital therapy. Dr. Rice uses clinical case examples to illustrate the following techniques: careful assessment of how the couple use their time; task assignments, beginning with the easier tasks; priority of attention to affective issues, especially anger, before addressing the specific areas of conflict; and the values of different forms of cotherapy.

The focus of understanding is largely transactional, with attention to how the dual-career marriage magnifies unresolved role and dependency problems that derive from families of origin. There is little attention to the study of intrapsychic issues, such as oedipal dynamics and separation-individuation. Larger systems and structural issues are also neglected to some degree. For example, the role of members of families of origin in the couple's current relationship are rarely addressed.

Apparently, Dr. Rice and his colleagues do not routinely see the couple's children. This omission risks overlooking the important questions of whether the children have been triangulated into the marital conflict and the developmental impairment they may suffer as a result of the marital stresses.

Overall, however, this is a useful book for therapists working with dual-career couples and for the couples themselves.

NORMAN I. MOSS, M.D.
Newton, Mass.

Psychopathology of Aging, *edited by Oscar J. Kaplan. New York, N.Y., Academic Press, 1979, 309 pp., $24.50.*

The editor defines the objectives of this book in his introduction:

> This book is a series of original essays on selected topics in geriatric psychiatry. It does not pretend to be encyclopedic in its coverage. However, it does seek to define the present frontiers in a number of significant areas.

How well does the book achieve this goal? The frontier persons, I suppose I must say, include veterans like Charles V. Ford and Lissy F. Jarvik on "Genetic Aspects of Psychopathological Disorders in Later Life," June E. Blum and Marcella Bakur Weiner on "Neurosis in the Older Adult," and some comparative newcomers like Robert H. Gerner, whose thorough review of "Depression in the Elderly" has 13 pages of references. Other chapters, such as "Acute, Reversible, Psychotic Reactions in Geriatric Patients" by Ivan N. Mensh, review work in the subject over the last decade.

Eugene Ziskind contributes an interesting chapter on "The Older Sociopath." He describes the six-year-old Gateways Research Project in which psychiatrists, psychologists, and social workers collaborated. This research, among other things, demonstrated defective laboratory conditioning of sociopathic subjects compared with control subjects.

Warren Breed and Carol L. Huffine write a thoughtful chapter on "Sex Differences in Suicide Among Older White Americans." They conclude that "differential socialization experiences will result in greater adaptability among girls in this society than among boys. These differences tend to be reinforced by typical adult role patterns of men and women and are ultimately reflected, we believe, in differential suicide rates" (p. 307). Some might disagree with their emphasis on adaptability as a major factor that depends, in turn, on socialization and developmental experiences. Such a concept appears too general to account for the well-known wish to die and its translation into weaker suicidal activity in physically ill elderly women compared with elderly men. The authors do not mention the observed fact that older women make more unsuccessful attempts at suicide than elderly men. Forced dependency through chronic ill health and self-hatred from feeling useless and a burden are readily observed in the elderly; presumably they affect men more than women. Here, adaptability as a factor seems less relevant.

Kaplan contributes an authoritative article on "Psychological Testing of Seniles." One of the minor irritations in the book is his persistent use of the undefined and pejorative adjective "senile" as a noun. He devotes considerable space to a description of his Psychological Abilities Scale for Seniles (PASS), evolved from a study he describes as "one of the most systematic and extensive ever undertaken on cogni-

tive functioning in seniles" (p. 60). Earlier in his introductory chapter he writes,

> Although it is unlikely that many cases [of late life dementia] will prove to be the result of some primary cause, such as slow-growing viruses or aluminum accumulation or genetic defect, a likely possibility is that a high percentage of the cases are of multiple causation and develop over a period of many years. This has led to the formulation of the Kaplan Cumulative Insult Theory, which postulates that some cases of senile dementia are the result of lifelong loss of cortical neurones through both "normal" aging and various pathological processes and events.

This begs the question, indeed.

Apart from occasional faults like these, Kaplan and his coauthors have drawn a helpful map of the frontiers in the psychopathology of aging. If some of them wander through treacherous swamps and fens, this is because our current knowledge is far too weak to allow us to draw them on firmer ground.

FRED B. CHARATAN, M.D.
New Hyde Park, N.Y.

Soviet Psychoprisons, *by Harvey Fireside. New York, N.Y., W.W. Norton & Co., 1979, 193 pp., $11.95.*

In the last few years there has been a flurry of books dealing with the Soviet misuse of psychiatry for political purposes. For example, Victor Nekipelov's *Institute of Fools* (1) describes the apex of such misuse—the Serbsky Forensic Psychiatry Institute, where he was briefly detained in 1973. Alexander Podrabindek, the young medical assistant who is in exile for publicizing the political use of psychiatry, has written a comprehensive account of the practice that tallies closely with an earlier report and analysis by Peter Reddaway and myself (2). Victims of the abuse have also detailed their experiences; particularly illuminating are those of Bukovsky and Plyuschch.

Fireside, a political scientist, has added to this expanding literature a brief, clearly written volume that brings the continuing "saga" up to date. There is a foreword by Zhores Medvedev, a distinguished geneticist who was himself detained for 19 days in the Kaluga Mental Hospital in 1970. His forcible admission was undoubtedly prompted by the political authorities who, realizing Medvedev's international reputation, resorted to psychiatric hospitalization in the hope that this would cause less unfavorable publicity than his arrest or deportation. The authorities miscalculated: a furor ensued both in the USSR and abroad, and Medvedev was quickly released. Despite Medvedev's gripping account of this episode (3), Western psychiatrists were somewhat incredulous in the early 1970s that their Soviet counterparts could have participated in such unethical practices. Since then the evidence of blatant and widespread abuse has become overwhelming. Now only a minority of Western psychiatrists agree with the Soviet defenders of their profession that the allegations of abuse are groundless and merely an "element in the cold war."

Fireside's book deals with several aspects of the abuse, including the motivations of the Soviet doctors involved, the victims, and opposition to the practices in the USSR and the West. The treatment of these topics is, however, rather brief and chiefly descriptive; little attempt is made at analysis. The second half of the book consists of several intriguing appendixes. Included is the "Manual on Psychiatry for Dissidents," a unique document co-authored by Bukovsky and Dr. Semyon Gluzman when they were interned for a short time in a labor camp together. The manual's chief purpose is to instruct human rights activists, would-be emigrants, religious dissidents, and others who have suffered at the hands of the KGB on how to deal with the psychiatrists who diagnose their "ideas of reformism" as evidence of severe mental illness. The manual also offers advice to the dissident on how to recant should he be unfortunate enough to be admitted to a mental hospital. The fact that there is a need for a manual of this kind is in itself an indictment of contemporary Soviet psychiatry.

Other appendixes are a summary of Podrabinek's book and personal accounts by three dissenters, Vladimir Gusarov, Oleg Solovyov, and Mikhail Kukobaka, of their psychiatric experiences. These accounts offer a vivid portrait of life inside both prison and civilian psychiatric hospitals.

It seems tragic that as we enter the 1980s there is still a need for books such as *Soviet Psychoprisons*. The story of Soviet abuse continues; dissidents are still detained in hospitals for nonmedical purposes, while those released live under the possibility of forcible readmission as long as they persist in their "political behavior." One hopes that the newly established Review Committee of the World Psychiatric Association, which is empowered to examine cases of abuse wherever they occur, will help to contribute to the closing of a shameful chapter in the history of psychiatry.

Applied Hypnosis and Hyperempiria, *by Don E. Gibbons. New York, N.Y., Plenum Press, 1979, 202 pp., $18.50.*

Hypnosis has become an acceptable method of treatment. According to the foreword of this book, "During the past twenty-five years, more research has been conducted on hypnosis than in all the preceding years since Mesmer." The book is well written and, for the most part, adequately documented. It contains 13 chapters, some of which are only 1–3 pages in length. The induction protocols are detailed and clearly presented. There are practical suggestions for the deepening of hypnosis, the retrieving of repressed or forgotten material, improved creativity and performance, and terminating the trance.

The blurb on the inside of the front cover states that this book is an "entirely new approach" called "hyperempiria" (a hyperexperience)—"a mind expanding induction technique based upon heightened awareness originated by the author."

The methodology is neither "new" nor "mind expanding" (1). Therapeutic results will probably be the same whether the induction suggestions are passive and sleeplike or more active and suggesting a heightened sensory awareness. The hypnotic experience is more than a "believed-in imagination" (according to Sarbin). The external behavioral aspects of hypnosis are artifacts that depend on the patient's expectations, what he or she has learned about hypnosis, and the operator's cues (according to Orne). The hypnotist only sets the stage. It is the subject who is actually in control. The subject is not a passive agent but an active participant who uses the hypnotist for his or her own needs (2).

Since this book is another "how to do it" text, all subjective reports of what is going on in the subject have been excluded. Hypnosis, however, is a type of effortless, receptive attention, which occurs only in a special relationship with a trusted guide, whom the subject has selected at a particular time in his or her illness and endowed with the power to heal (to alleviate anxiety, expiate guilt, reduce pain, and expedite the recall of significant traumatic memories) (2).

Chapter 1 ("The Nature of the Induction Process") contains two significant historical errors. The first is that Puységur's patient, who became the prototype of "artifical somnambulism," was named Victor Race, not Victor Immanuel. This patient's sleeplike, "lucid" trance state was not "first manifested by people who were imitating the behavior of a retardate, who was too stupid to realize that he was supposed to go into convulsions (Mesmer's crisis) and went to sleep instead" (p. 5).

The author has altogether overlooked the historical significances of Puységur's momentous discovery of the "new" magnetism, which, as Ellenberger (3) indicated, "gave a new course to the evolution of 'animal magnetism.' . . . This discovery equals or exceeds the importance of Mesmer's work." The real founder of modern hypnosis is Puységur. It was from Victor Race that he learned that magnetism should not be used for public demonstrations (Victor became worse or refused to perform) but only for therapeutic purposes. Puységur also learned that the "pure crisis" (artificial somnambulism) involved not only the will of the magnetizer but also the rapport between the operator and his subject; this made Mesmer's theories scientifically preposterous. Puységur determined that Victor was brighter and more alert in the trance than in his normal state, that he had no memory of having been magnetized (spontaneous amnesia), and that he thought that he could diagnose his own and other patients' diseases and could prescribe treatment while in the trance.

The second error is the incorrect description of the classical Braid technique of hypnotic induction. Braid did not "swing" a bright shining object "back and forth" while giving the subject "a steady stream of suggestions to the effect that his eyes are becoming heavy" and "that he will want to close them" (pp. 12, 43).

Braid (4) wrote,

> Take any bright object, hold it about 8 to 15 inches from the eyes, at such position above the forehead as may be necessary to produce the *greatest possible strain* upon the eyes. . . . The patient *must* be made to understand that he is to keep his mind *riveted on the idea of that one object*.

Braid *never* used suggestions of eye heaviness. This type of induction was Liebault's contribution, which was taken over by Bernheim.

The author briefly describes various hypnotic models, including Orne's trance logic in the state of altered consciousness, Hilgard's neodissociation hypothesis, Coe and Sarbin's role-playing paradigm, Gill and Brenman's transference-regression theory, and Barber's social-psychological variables. It is Gibbons' opinion that "trance logic, rapport, transference, and disassociation phenomena are *all* products of suggestion, rather than the trance state itself." He takes no special position in regard to any of these models and states, "If usefulness rather than 'Truth' becomes the criterion by which various models are to be evaluated, it follows that models which initially appear to be quite different from one another need not be considered as mutually exclusive."

This "how-to-do-it" text will be of value to beginners, who need to learn what to say during the initial induction procedure. The book represents a start and requires that its reader learn more about the psychodynamics of the trance relationship and its meaning to the patient.

Between Reality and Fantasy: Transitional Objects and Phenomena, *edited by Simon A. Grolnick, M.D., and Leonard Barkin, M.D., in collaboration with Werner Muensterberger, Ph.D. New York, N.Y., Jason Aronson, 1978, 555 pp., $30.00.*

This volume is substantially a memorial to the personality and work of the late Donald W. Winnicott. Winnicott's more than 40 years as a practicing pediatrician, during which he had countless rich opportunities for the observation of behavior in children, and his many years as a clinical psychoanalyst, during which he was able more systematically to explore the inner workings of the minds of not only children but also adults, put him in a unique position to explore and contribute to our understanding of the interplay between childhood experience and adult personality. Because of Winnicott's personality, however, his contributions tend to be more genial and inspirational than systematic or carefully elaborated. His genial inspirations rose out of the chaos of his own struggles to understand, a view that Winnicott was not slow to articulate.

As is so often the case with explorations of the fragile boundaries of any science, inspired forages must be followed by attempts of a more systematic and plodding nature to sort out the territory, to integrate what has been discovered with what is already known, and to tidy up the mess. *Between Reality and Fantasy* represents an effort to tidy up a bit, without carrying the impetus of Winnicott's contribution forward to any noteworthy extent. Much of the tidying up has to do with clarifying and specifying what precisely is meant by "transitional object" and "transitional phenomena." Winnicott used terms somewhat loosely, and there is a need

for clarifying the transitional usage from issues of pathological infantile fetishism on the one hand and problems of perception and apperception on the other. Questions in definition arise; for example, the extent to which and the manner in which the transitional object comes to replace the mother and whether it attains a greater valence for the child than does the person of the mother herself. An additional matter has to do with the extent of parental involvement in the choice of transitional object and in the emergence of the transitional phenomenon itself. These are all matters of degree and involve a spectrum of transitional phenomena that require further delineation and discussion.

An effort is made in several pieces to extend more deeply the empirical basis on which the transitional schema builds. This effort is carried on primarily by child analysts and psychiatrists and has immediate relevance to concerns about personality development. The attempts at theoretical integration seem somewhat more tenuous. Efforts are made to integrate Winnicott's insights with the work of Spitz, for example, and with early matters of physiological regulation in the interaction between mother and child. Some of this must be considered highly speculative, and a word of caution is indicated because the authors engaged in this speculative venture are not always clear as to what is actually a theoretical extension of Winnicott's formulations and what may be venturesome speculation.

One of the more important sections of the book is a series of clinical studies that attempt to apply Winnicott's notion of transitional phenomena to aspects of clinical work. Subjects covered include the "analyzing instrument," transferences, dreaming phenomena, self-object relations, obsessive-compulsive states, and particular forms of clinical manifestation such as friendships, attachments to cats, infantile fetishes, and delusions.

Following Winnicott's observation that transitional phenomena are the basis for the development of illusion, which includes the locus of cultural experience, there is a rather fascinating section on extensions of the transitional frame of reference to aspects of human creativity. Particular studies address themselves to Etruscan burial symbols, transitional language usage, and poetic imagery in the work of Gerard Manley Hopkins and Emily Dickinson. Particularly noteworthy and disappointing here is the lack of an examination of the role of transitional phenomena in religious experience.

Fortunately, and refreshingly I might add, dissenting voices who sing *extra choram* are included in the book. Anthony Flew's acute and telling critique of the inherent logic of Winnicott's formulations deserves thoughtful and careful reading as a helpful corrective to the sometimes too easy extension of the notions of transitional phenomena and illusion to broad and somewhat diffuse areas of human experience.

All in all, I consider this volume a substantial contribution to the psychoanalytic and psychiatric literature, one that brings a greater degree of substance and articulation to the often amorphous if intuitive and tantalizing formulations in Winnicott's work. Clinicians who admire Winnicott's contributions will find their thinking in many areas of application to be considerably deepened and amplified. Those who are drawn to try to integrate Winnicott's thinking in a more systematic or theoretical way will come away sobered but, I think, not discouraged.

Working with the Impulsive Person, *edited by Howard A. Wishnie and Joyce Nevis-Olesen. New York, N.Y., Plenum Press, 1979, 184 pp., $19.50.*

Impulsivity has a long heritage in psychiatry. Many of the profession's pioneers, such as Freud, Fenichel, and Alexander, described impulsivity and acting out and wrote about impulsive characters; later workers, such as Greenacre and Johnson, shed light on the problems of acting out and the etiologies of antisocial impulsivity. In spite of the wealth of theoretical material, however, there is a paucity in the literature on the treatment of impulsive patients. Many clinicians are interested in the phenomenology of impulsivity but are disdainful of the treatment of these patients and stay away from them.

This volume contains papers on etiology, clinical approaches, the criminal justice system, and a historical overview. The tone of the book is psychodynamic, and most contributors spend time on intrapsychic mechanisms. The first three chapters deal with early childhood development, object relations theories, and criminologic considerations. The next group of papers are more therapeutically oriented and deal with alliances. There are two papers on drug abuse that have a theoretical flavor. Dr. Wishnie's own chapter on panic states summarizes some material presented in his previous fine book titled *The Impulsive Personality* (1). I enjoyed his vignettes and diagrammatic conceptualizations of impulsive behavior. A final section of the book is more forensic in nature and deals with legal decisions affecting violence and dangerousness.

The chapters are very uneven in quality. If I had my way, I would have published only the clinical approaches because we have been deluged with theory and need more practical management techniques. One omission from the book is any discussion of important developments in the neurophysiology of impulsivity. Monroe (2) and others have made important contributions toward the biologic understanding of impulsivity. Such work, together with the observations made by Dr. Wishnie, gives therapeutic insight into behaviors that otherwise appear perplexing and chaotic.

DSM-III

The American Psychiatric Association's First Major Revision of the Psychiatric Nomenclature in 12 Years

This long awaited revision of the **Diagnostic and Statistical Manual of Mental Disorders** has taken five years to develop and field test. The result is a 500-page text which is unsurpassed in its completeness, clinical reliability, and description of criteria and codes for psychiatric diagnostic classification. The book incorporates a revision of the diagnostic classifications of DSM-II with an extensive listing of new diagnostic criteria, decision trees for differential diagnosis, a glossary of technical terms, an annotated comparative listing of DSM-II and DSM-III classifications, an historical review of ICD-9 and ICD-9-CM classifications, and field trials presenting interrater reliability and a listing of participants. Multiaxial evaluation charts are included to assist the reader in establishing treatment planning and prediction of outcome.

A Compact, Quick-Reference Guide

In making a DSM-III diagnosis, clinicians and researchers may find it convenient to consult the **Quick Reference to the Diagnostic Criteria,** a pocket-sized booklet that contains only the classification, the diagnostic criteria, and a listing of the most important conditions to be considered in a differential diagnosis of each category.

Order Now. Mail coupon to The American Psychiatric Association, Publication Sales, 1700 18th Street, N.W., Washington, D.C. 20009.

Please send me _____ copies of **DSM-III** (hardbound edition), Order #143 @ $25.00.

_____ copies of the **DSM-III** (paperback edition), Order #143-1 @ $20.00.

_____ copies of the **Quick Reference to the Diagnostic Criteria** (paperback), Order #144 @ $10.00

_____ sets (Hardbound **DSM-III** and **Quick Reference to the Diagnostic Criteria**), Order #407 @ $31.00.

Bulk discounts: 10–24 copies, 10% discount per title; 25–99 copies, 15% discount per title; 100 or more copies, 20% discount per title. No bulk discount is available on the Set.

ENCLOSED IS A TOTAL PAYMENT OF $ _____.

(All domestic orders amounting to $35.00 or less must be accompanied by payment. All foreign orders, regardless of dollar amount, must be accompanied by payment. Non-prepaid orders (over $35.00) will be invoiced with shipping/handling charges included.)

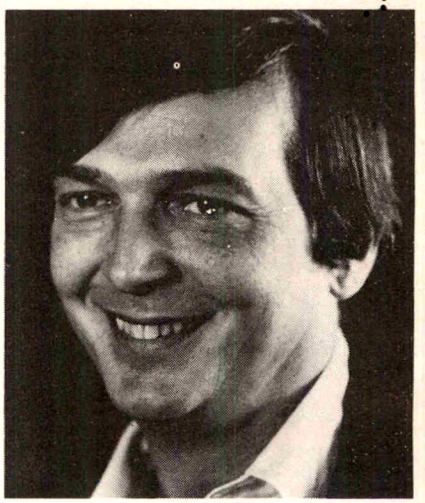
Why Red Cross CPR training is good for your business...

Take it from Andy Machak, automotive electrical plant foreman: "I'm alive today because a fellow employee was trained in CPR.

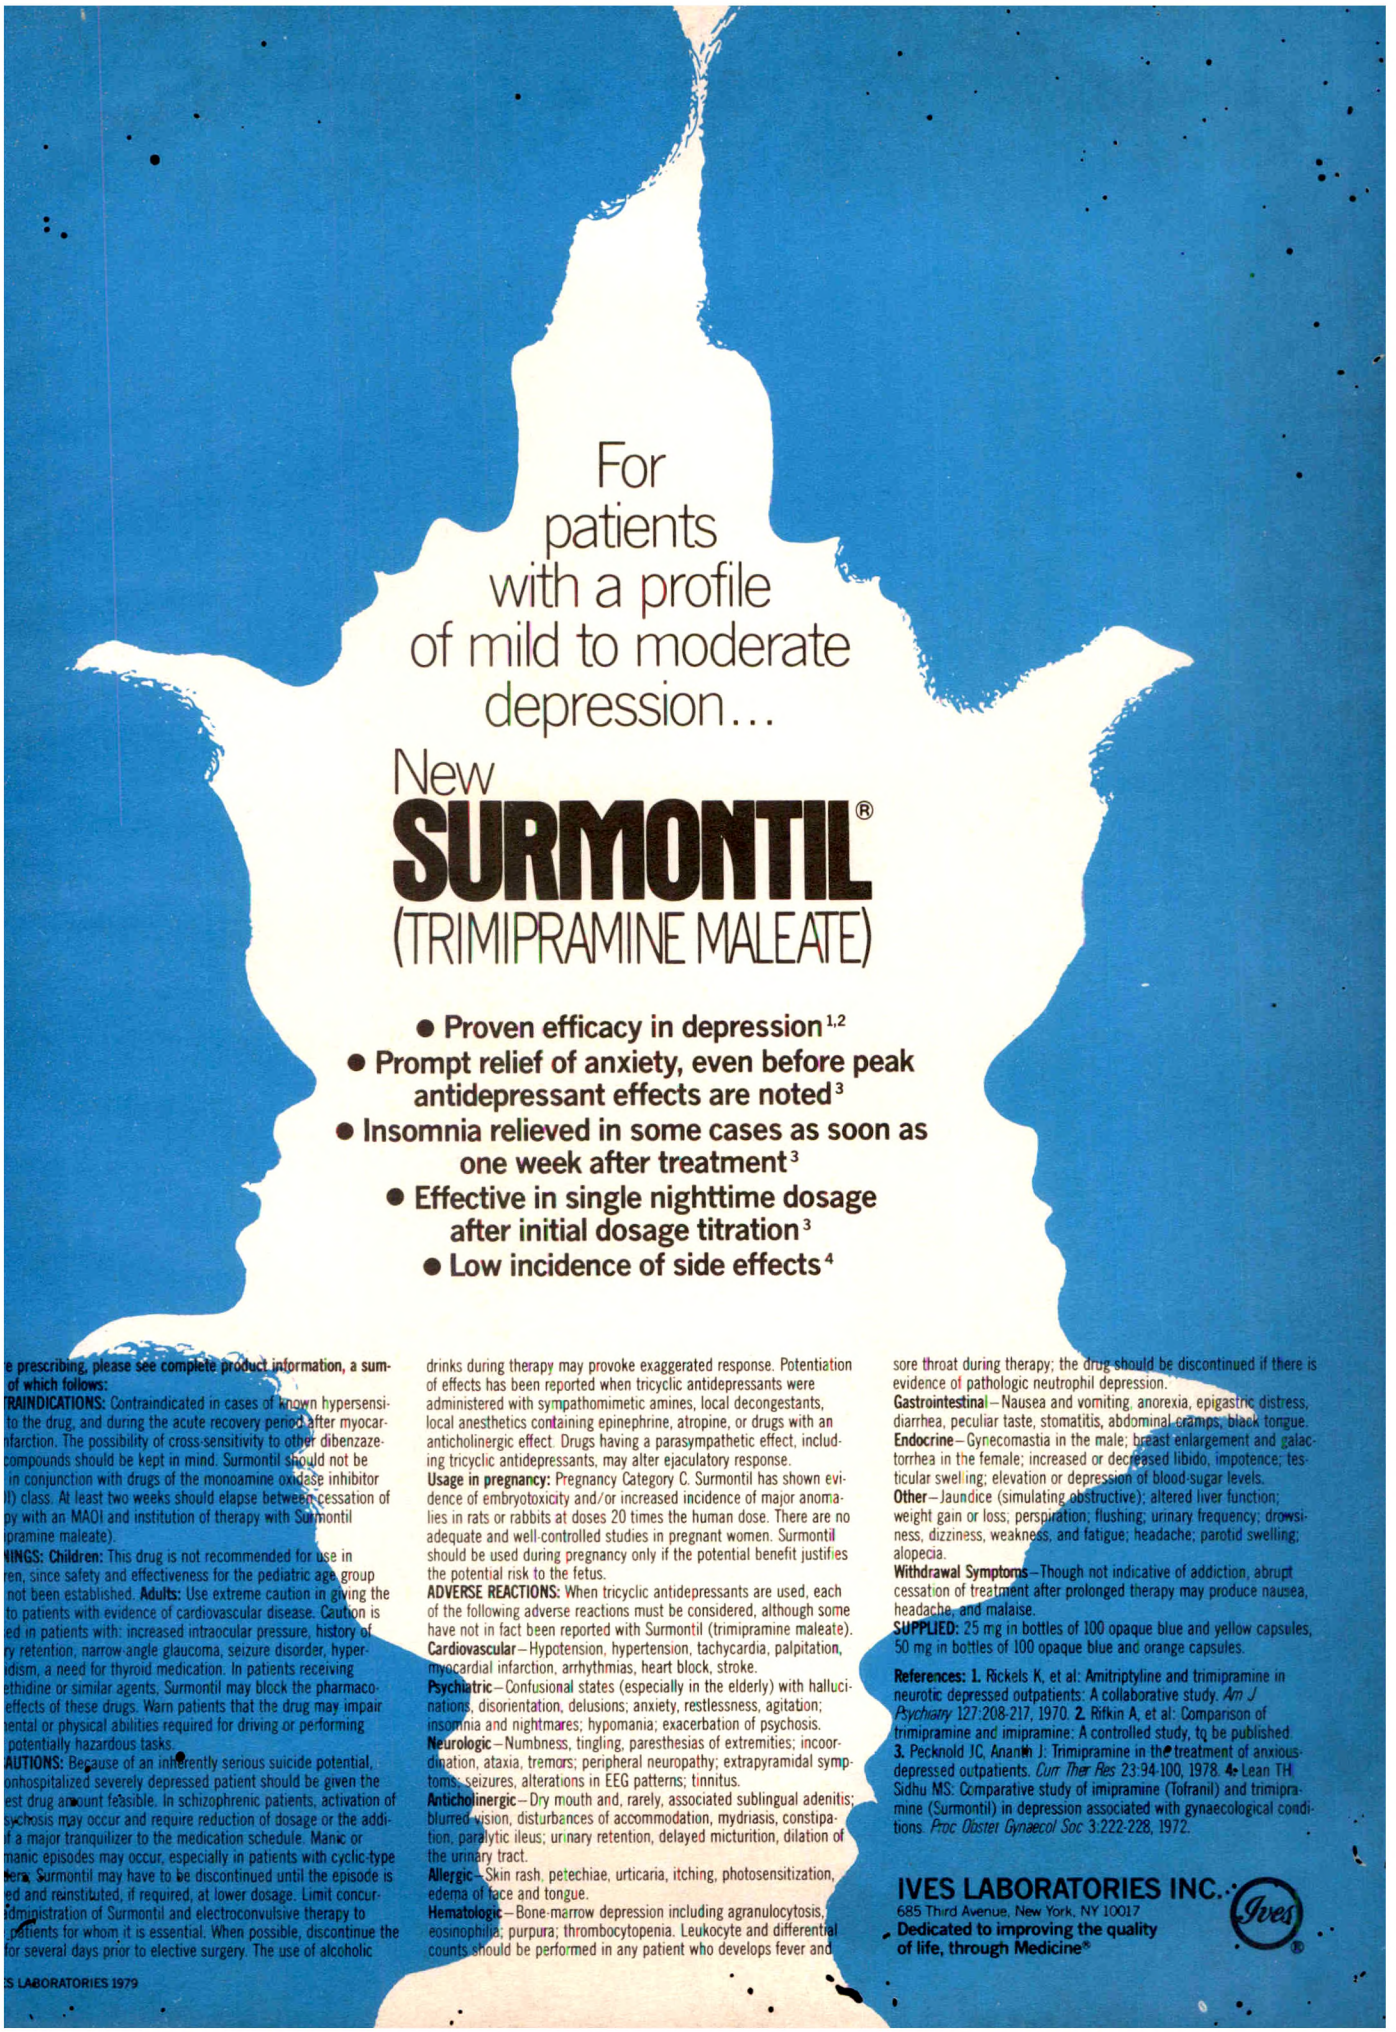


"Cardiopulmonary resuscitation training was one valuable asset that day. I got caught in some heavy machinery at the plant and blacked out.

"They told me later it took six guys to free me. I wasn't breathing. My heart stopped. One of the guys, Don Guarino, said, 'I gotta try anyway.'

"Thanks to his CPR training, he revived me – saved my life.

"Since that happened I realize that no employee is immune from heart attacks or accidents, and a few CPR-trained employees – maybe one for every 50 people – can make the difference between life and death."



Call your Red Cross Chapter and find out about CPR training for your plant or office. CPR training is a valuable asset for any business.

It takes steady, trained hands to perform CPR.

American Red Cross

e prescribing, please see complete product information, a sum- of which follows:

TRAINDICATIONS: Contraindicated in cases of known hypersensi- to the drug, and during the acute recovery period after myocar- nfarction. The possibility of cross-sensitivity to other dibenzaze- compounds should be kept in mind. Surmontil should not be in conjunction with drugs of the monoamine oxidase inhibitor I) class. At least two weeks should elapse between cessation of py with an MAOI and institution of therapy with Surmontil ramine maleate).

NINGS: Children: This drug is not recommended for use in ren, since safety and effectiveness for the pediatric age group not been established. **Adults:** Use extreme caution in giving the to patients with evidence of cardiovascular disease. Caution is ed in patients with: increased intraocular pressure, history of ry retention, narrow-angle glaucoma, seizure disorder, hyper- idism, a need for thyroid medication. In patients receiving ethidine or similar agents, Surmontil may block the pharmaco- effects of these drugs. Warn patients that the drug may impair ental or physical abilities required for driving or performing potentially hazardous tasks.

AUTIONS: Because of an inherently serious suicide potential, onhospitalized severely depressed patient should be given the est drug amount feasible. In schizophrenic patients, activation of sychosis may occur and require reduction of dosage or the addi- f a major tranquilizer to the medication schedule. Manic or manic episodes may occur, especially in patients with cyclic-type hera. Surmontil may have to be discontinued until the episode is ed and reinstituted, if required, at lower dosage. Limit concur- dministration of Surmontil and electroconvulsive therapy to patients for whom it is essential. When possible, discontinue the for several days prior to elective surgery. The use of alcoholic drinks during therapy may provoke exaggerated response. Potentiation of effects has been reported when tricyclic antidepressants were administered with sympathomimetic amines, local decongestants, local anesthetics containing epinephrine, atropine, or drugs with an anticholinergic effect. Drugs having a parasympathetic effect, includ- ing tricyclic antidepressants, may alter ejaculatory response.

Usage in pregnancy: Pregnancy Category C. Surmontil has shown evi- dence of embryotoxicity and/or increased incidence of major anoma- lies in rats or rabbits at doses 20 times the human dose. There are no adequate and well-controlled studies in pregnant women. Surmontil should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

ADVERSE REACTIONS: When tricyclic antidepressants are used, each of the following adverse reactions must be considered, although some have not in fact been reported with Surmontil (trimipramine maleate).

Cardiovascular—Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric—Confusional states (especially in the elderly) with halluci- nations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic—Numbness, tingling, paresthesias of extremities; incoor- dination, ataxia, tremors; peripheral neuropathy; extrapyramidal symp- toms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic—Dry mouth and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis, constipa- tion, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

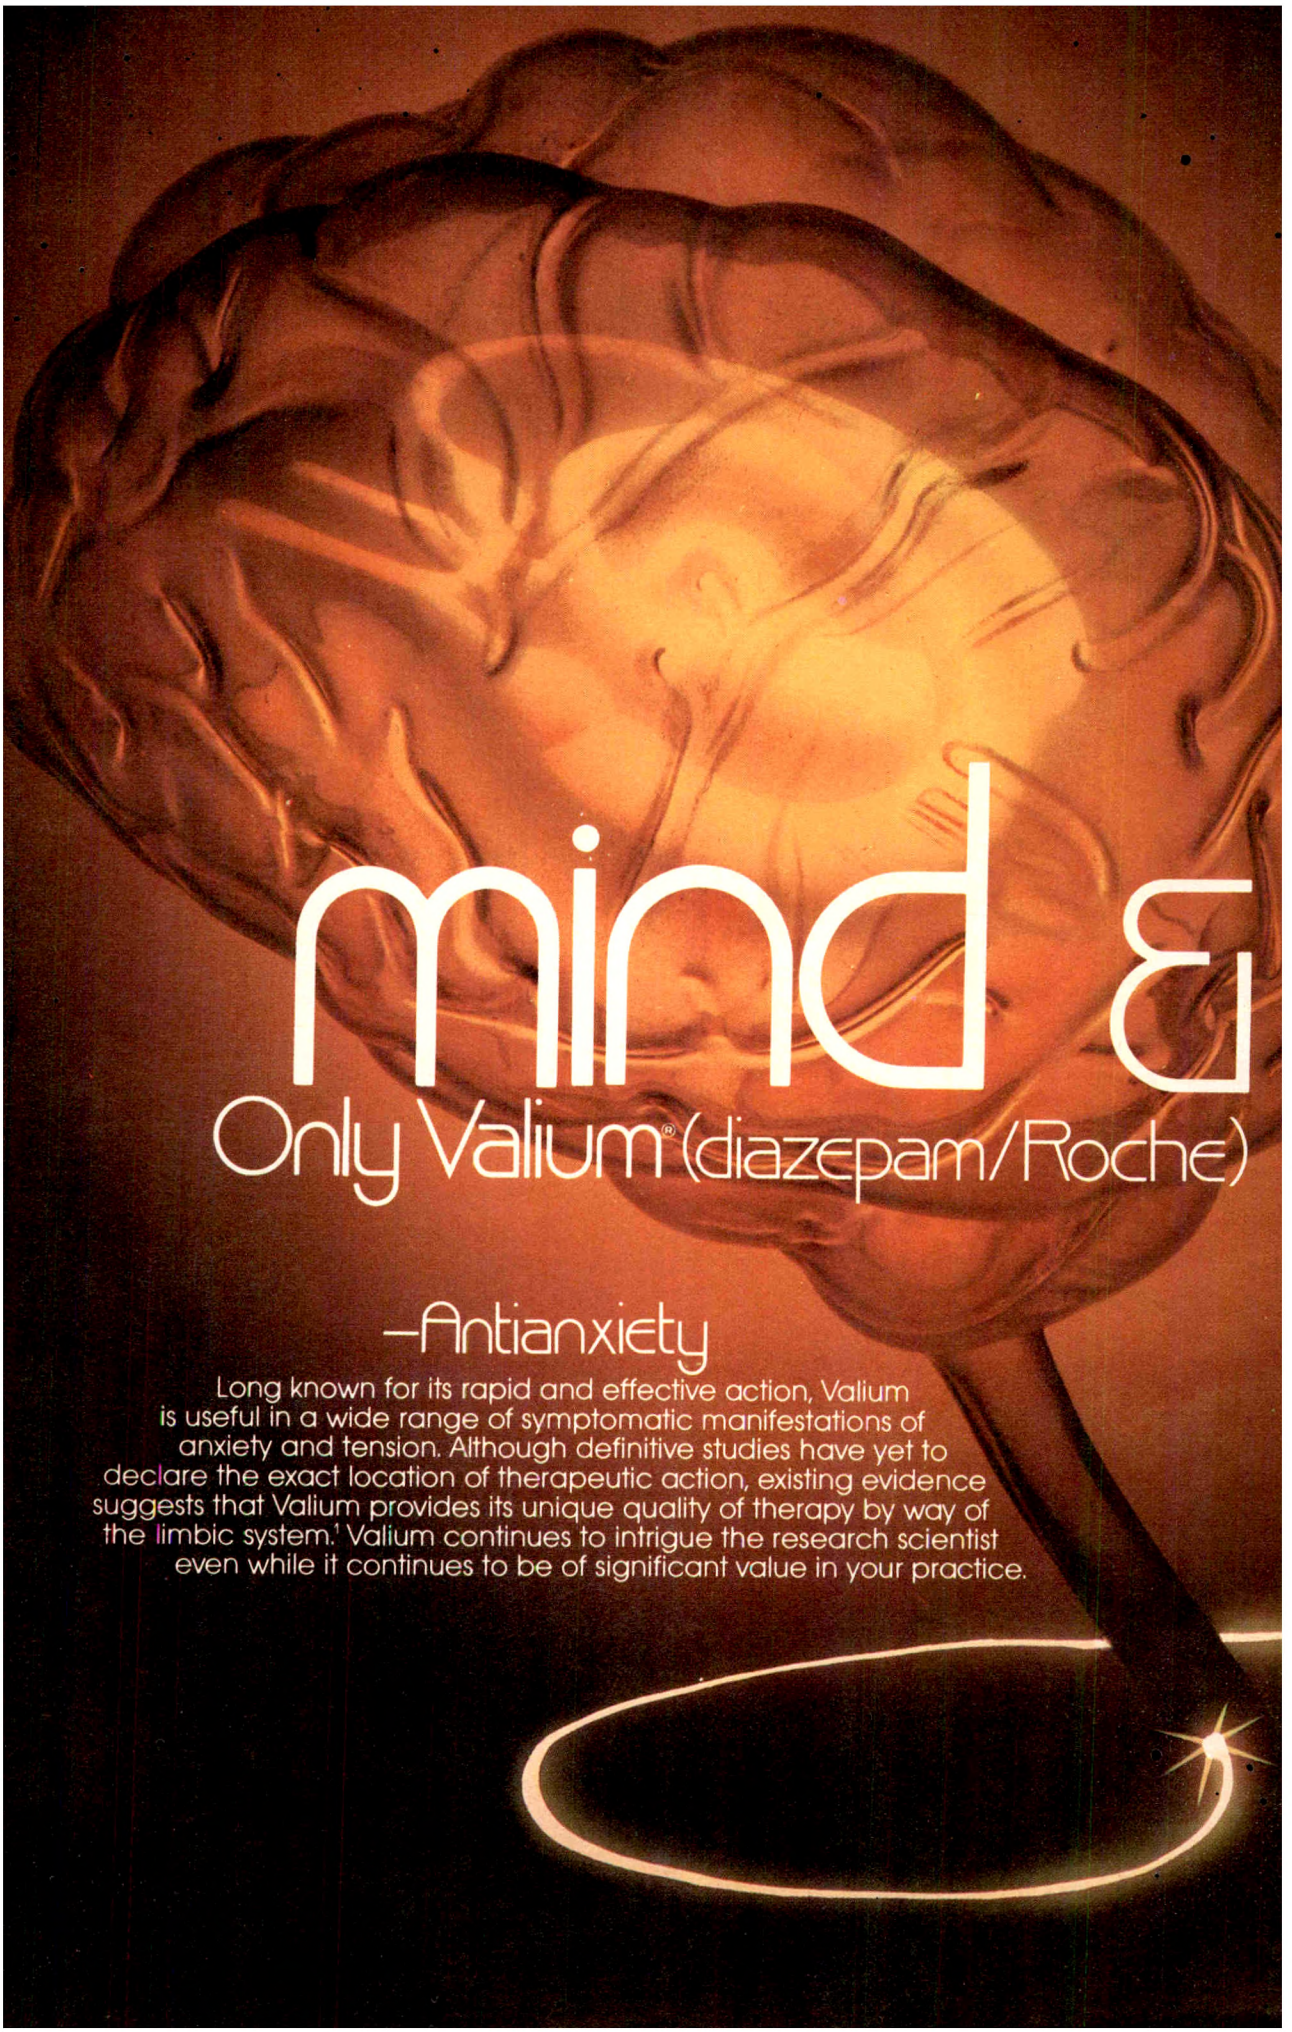
Allergic—Skin rash, petechiae, urticaria, itching, photosensitization, edema of face and tongue.

Hematologic—Bone-marrow depression including agranulocytosis, eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

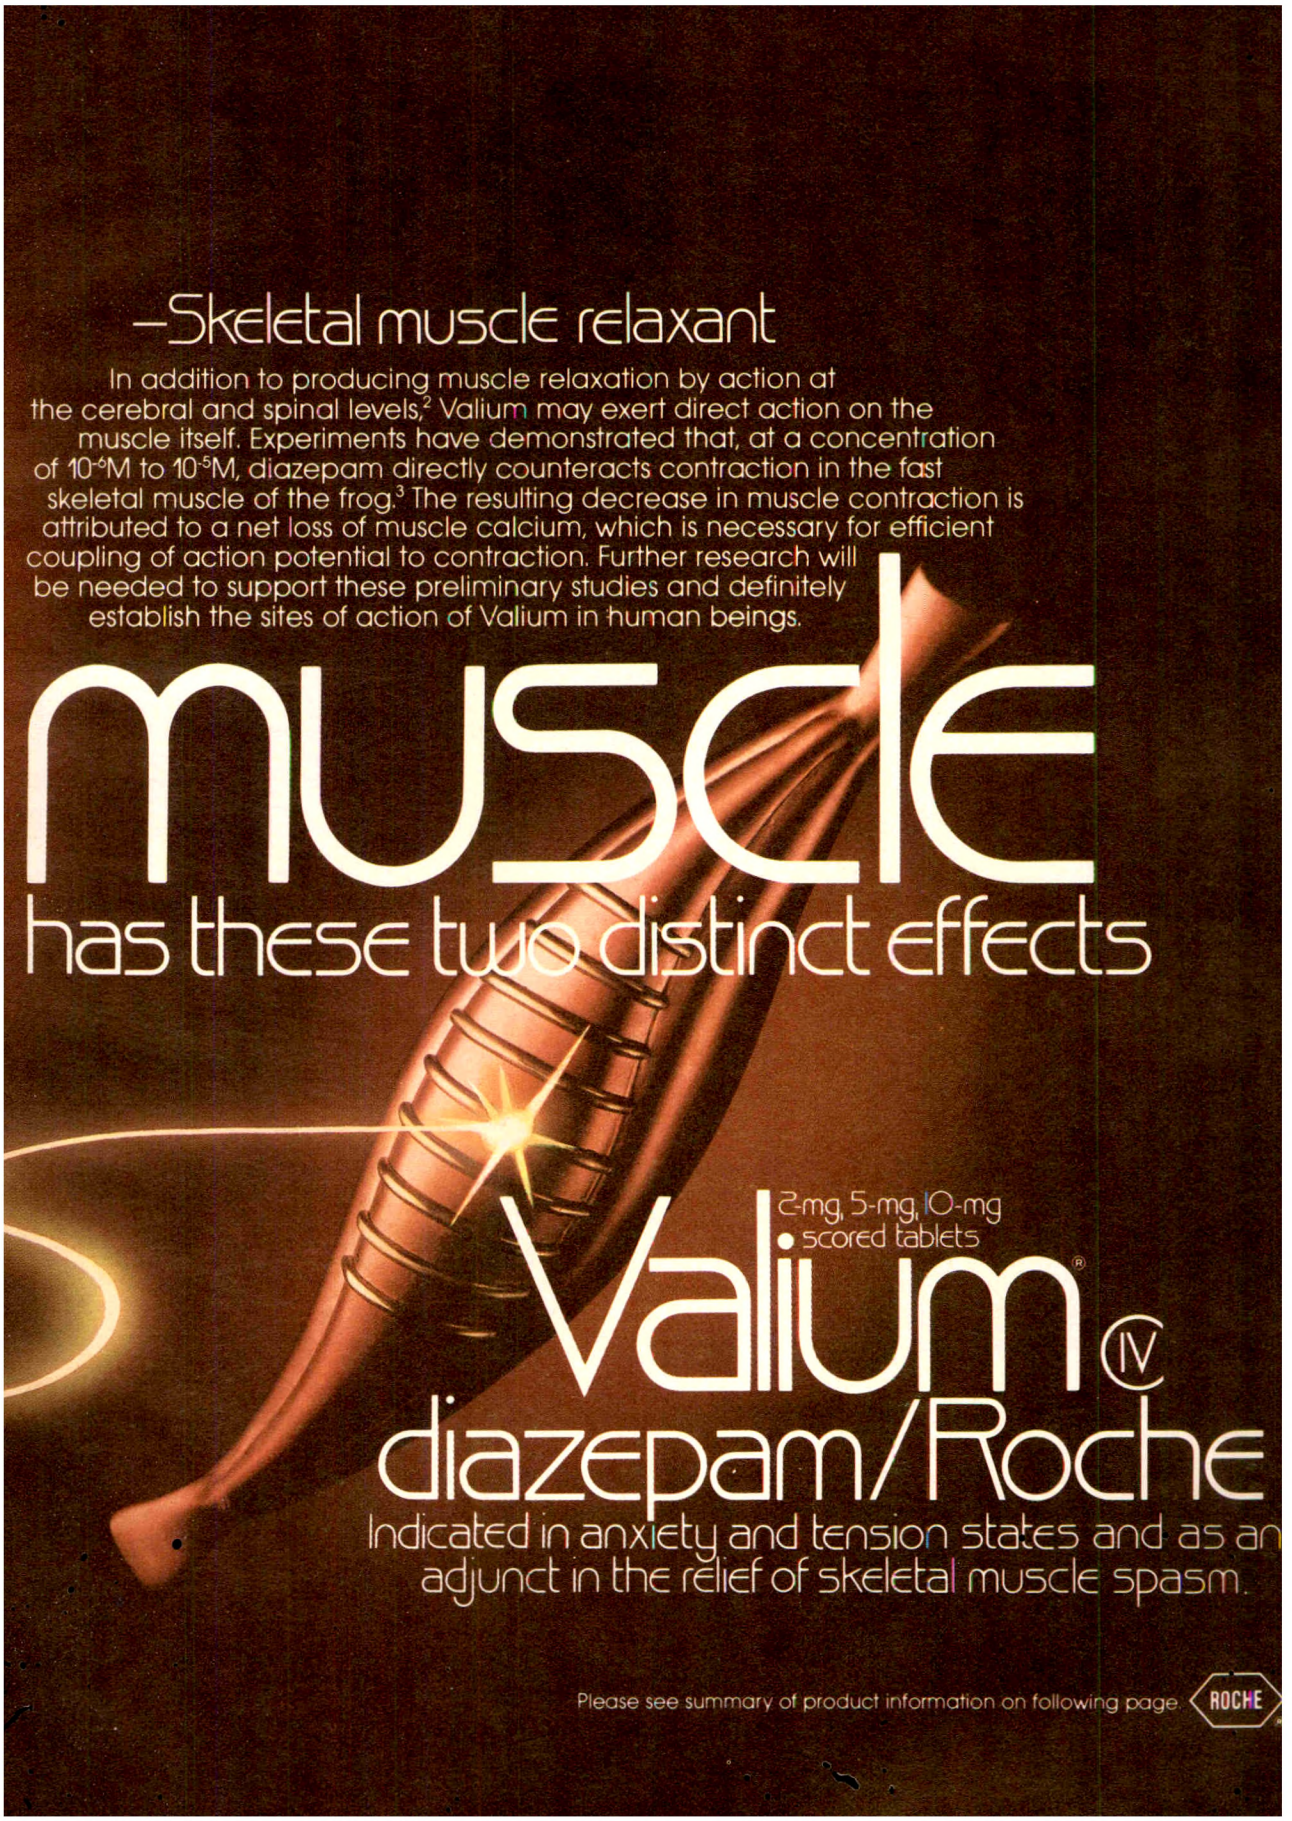
Gastrointestinal—Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine—Gynecomastia in the male; breast enlargement and galac- torrhea in the female; increased or decreased libido, impotence; tes- ticular swelling; elevation or depression of blood-sugar levels.

Other—Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsi- ness, dizziness, weakness, and fatigue; headache; parotid swelling; alopecia.



Withdrawal Symptoms—Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.



SUPPLIED: 25 mg in bottles of 100 opaque blue and yellow capsules, 50 mg in bottles of 100 opaque blue and orange capsules.

S LABORATORIES 1979

mind &
Only Valium® (diazepam/Roche)
–Antianxiety
Long known for its rapid and effective action, Valium is useful in a wide range of symptomatic manifestations of anxiety and tension. Although definitive studies have yet to declare the exact location of therapeutic action, existing evidence suggests that Valium provides its unique quality of therapy by way of the limbic system.' Valium continues to intrigue the research scientist even while it continues to be of significant value in your practice.

–Skeletal muscle relaxant
In addition to producing muscle relaxation by action at the cerebral and spinal levels,[2] Valium may exert direct action on the muscle itself. Experiments have demonstrated that, at a concentration of 10^{-6}M to 10^{-5}M, diazepam directly counteracts contraction in the fast skeletal muscle of the frog.[3] The resulting decrease in muscle contraction is attributed to a net loss of muscle calcium, which is necessary for efficient coupling of action potential to contraction. Further research will be needed to support these preliminary studies and definitely establish the sites of action of Valium in human beings.

Valium®
diazepam/Roche
Indicated in anxiety and tension states and as an adjunct in the relief of skeletal muscle spasm.
Please see summary of product information on following page.
ROCHE

Only Valium® (diazepam/Roche) is indicated in anxiety and tension states and as an adjunct in the relief of skeletal muscle spasm

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety associated with anxiety disorders, transient situational disturbances and functional or organic disorders; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).
The effectiveness of Valium (diazepam/Roche) in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should periodically reassess the usefulness of the drug for the individual patient.

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms similar to those with barbiturates and alcohol have been observed with abrupt discontinuation, usually limited to extended use and excessive doses. Infrequently, milder withdrawal symptoms have been reported following abrupt discontinuation of benzodiazepines after continuous use, generally at higher therapeutic levels, for at least several months. After extended therapy, gradually taper dosage. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

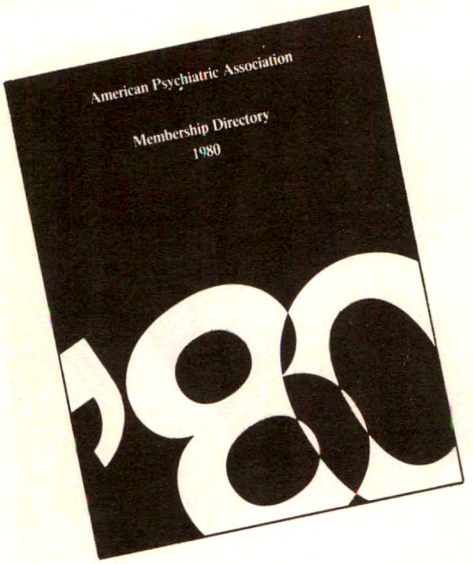
Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available in trays of 10.



General guidelines for the prescribing and appropriate use of minor tranquilizers

- Individualize dosage for maximal beneficial effect.
- Prescribe the specific quantity needed until the next checkup period, schedule frequent, periodic reexaminations to monitor results of therapy.
- Establish treatment goals and gradually discontinue medication when these have been met.
- Avoid prescribing for individuals who appear dependency-prone or whose histories indicate the potential for misuse of psychoactive substances, including alcohol.
- Caution patients against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving.
- Advise patients against the ingestion of alcoholic beverages while undergoing therapy with minor tranquilizers.
- Counsel patients to follow label directions, keep medication out of children's reach, and dispose of unused or old medication.
- Caution patients against giving medication to others.
- Avoid abrupt cessation of extended therapy by tapering dosage before discontinuing medication.

Order Your Copy of the 1980 Membership Directory Now!

The latest listing of APA members (as of January 31, 1980) has just been published. Unlike previous editions, the 1980 Membership Directory, largely at the urging of President Dr. Donald G. Langsley, contains telephone numbers as well as names, addresses, membership class and membership status. A new format provides easy access to the alphabetical and geographical listings.

Another new addition to this Directory is a section containing the names and addresses of District Branch Executive Secretaries. Also included in this Directory is a list of Officers, the Board of Trustees and the Assembly, as well as past APA meetings, past Officers, Honorary and Distinguished Fellows and a membership table. This publication will provide readers with information about the APA and the most comprehensive listing of the membership since the 1977 Biographical Directory.

April 1980. Approximately 300 pages. Order #151. $13.00.

Help cure cancer write now.

Thanks to your help, the tide is beginning to turn. The past few years have brought new discoveries in chemotherapy.

And new diagnostic techniques that combine the "eyes" of X-ray machines with the "brains" of computers. And successful new programs of combination therapies.

And there are promising reports coming in from research laboratories all over the world.

We now have everything we need to save about half the people who get cancer.

Please don't quit on us now.

We're halfway there.

American Cancer Society®

We want to cure cancer in your lifetime.

This space contributed by the publisher as a public service.

Lithobid™

Slow-Release Lithium Carbonate 300 mg.

Before prescribing, see complete prescribing information in Rowell literature. The following is a brief summary.

WARNING
Lithium toxicity is closely related to serum lithium levels, and can occur at doses close to therapeutic levels. Facilities for prompt and accurate serum lithium determinations should be available before initiating therapy.

Indications: Treatment of manic episodes of manic-depressive illness. Maintenance therapy prevents or diminishes the intensity of subsequent episodes in manic-depressive patients with a history of mania.

Warnings: Lithium should generally not be given to patients with significant renal or cardiovascular disease, severe debilitation or dehydration, sodium depletion, or to patients receiving diuretics.

Lithium therapy has been reported in some cases to be associated with morphologic changes in the kidneys.

Caution patient and family to watch for diarrhea, vomiting, tremor, mild ataxia, drowsiness, or muscular weakness as signs of lithium toxicity, and to discontinue therapy and contact a physician should they occur. Patients receiving combined therapy with lithium and an antipsychotic should be monitored closely for early evidence of neurologic toxicity and treatment discontinued promptly if such signs appear. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery).

Lithium should not be used in pregnancy, especially during the first trimester, unless potential benefits outweigh possible hazards.

Not recommended for children under 12.

Precautions: Lithium tolerance is greater during the acute manic phase and decreases when manic symptoms subside.

Lithium therapy may lead to sodium depletion. Normal diet (including salt) and adequate fluid intake (2500-3000 ml) must be maintained, at least during initial stabilization period. Protracted sweating or diarrhea can decrease tolerance; in such cases, administer supplemental fluid and salt.

Each tablet contains 40 mg of sodium chloride, equivalent to 15.7 mg of sodium.

Sweating, diarrhea, and concomitant infection with elevated temperatures may require temporary reduction or cessation of dosage.

Adverse Reactions: Mild to moderate toxic reactions may occur at serum lithium levels from 1.5 to 2.5 mEq/L, and moderate to severe reactions at levels from 2.0 to 2.5 mEq/L. Fine hand tremor, polyuria, and mild thirst may occur during initial therapy and persist. Transient and mild nausea and general discomfort also appear during initial therapy. These effects usually subside with continued treatment or temporary reduction or cessation of dosage. If persistent, discontinue dosage.

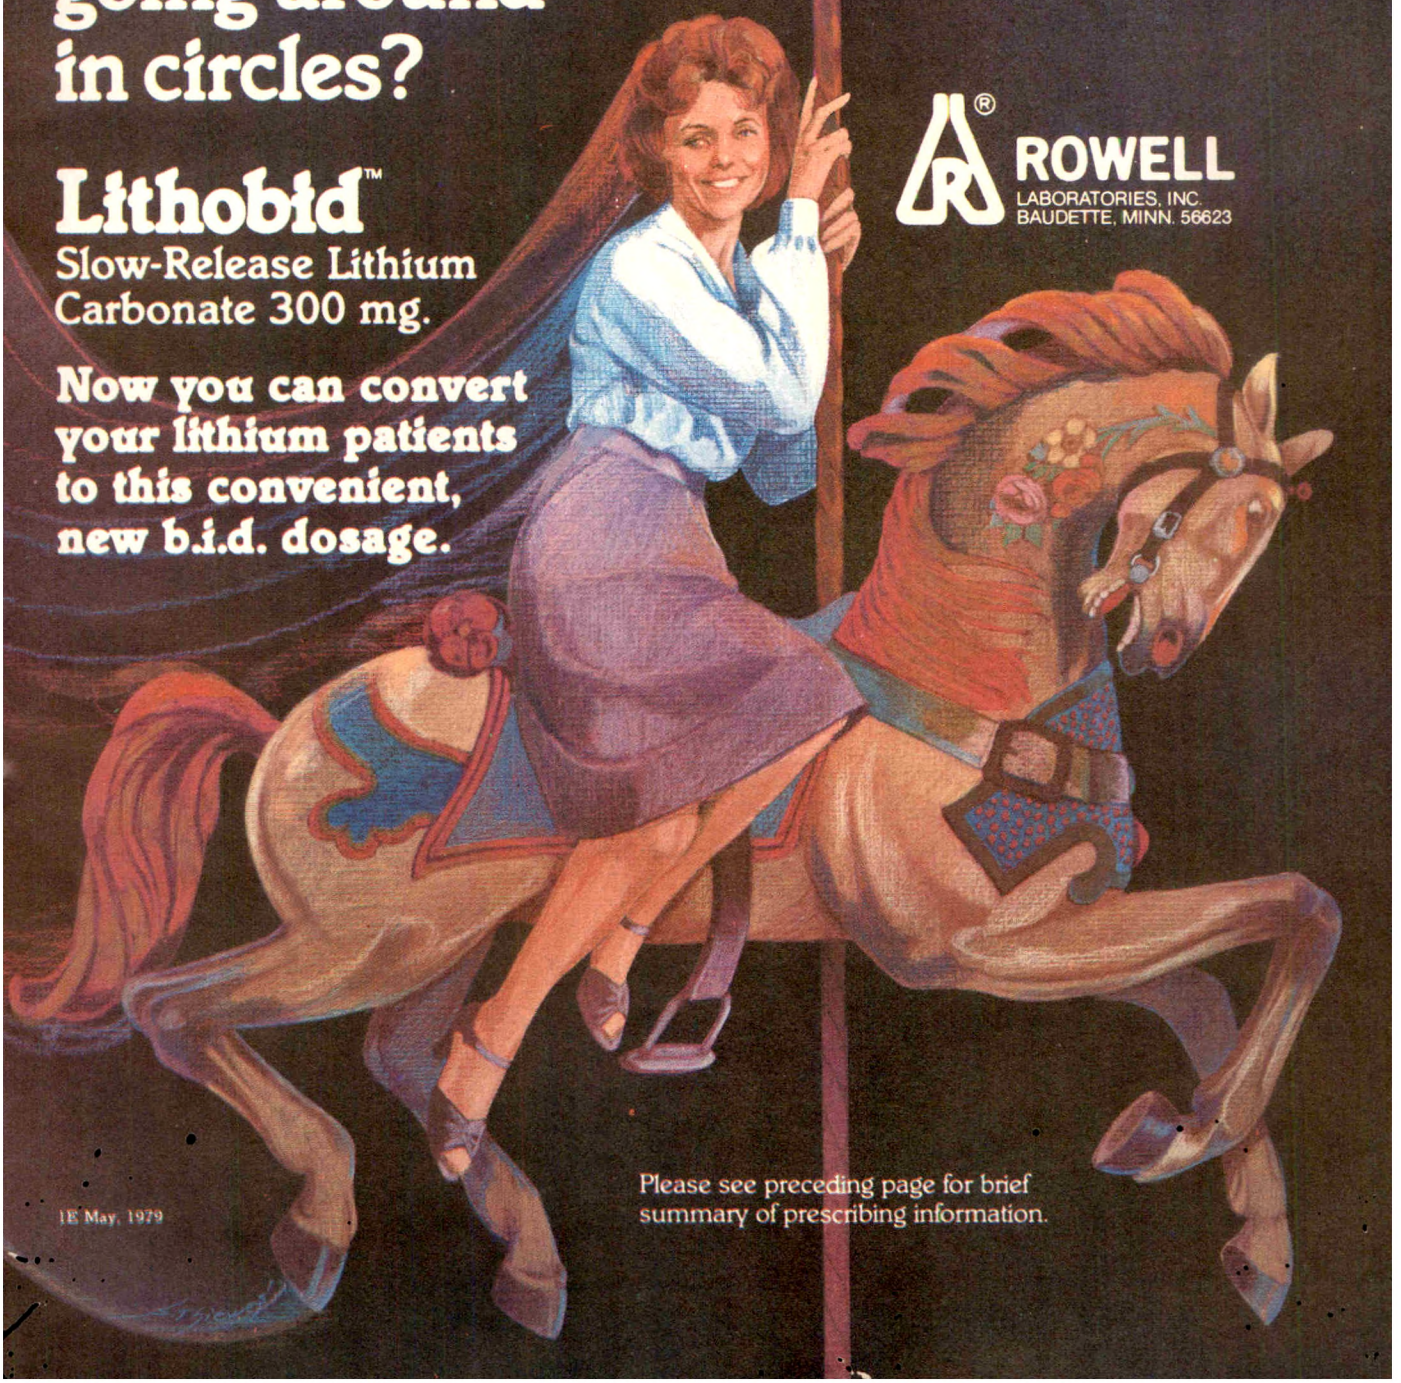
Diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination may be early signs of toxicity and may occur at levels below 2.0 mEq/L. At higher levels, ataxia, giddiness, tinnitus, blurred vision, and a large output of dilute urine may be seen. Serum levels above 3.0 mEq/L may produce a complex clinical picture, involving multiple organs and systems. Serum levels should not exceed 2.0 mEq/L during acute phase.

The following reactions appear to be related to serum lithium levels, including levels within the therapeutic range: Neuromuscular—tremor, muscle hyperirritability (fasciculations, twitching, clonic movements of whole limbs), ataxia, choreo-athetotic movements, hyperactive deep tendon reflex; Central Nervous System—blackout spells, epileptiform seizures, slurred speech, dizziness, vertigo, incontinence of urine or feces, somnolence, psychomotor retardation, restlessness, confusion, stupor, coma; Cardiovascular—cardiac arrhythmia, hypotension, peripheral circulatory collapse; Gastrointestinal—anorexia, nausea, vomiting, diarrhea; Genitourinary—albuminuria, oliguria, polyuria, glycosuria; Dermatologic—drying and thinning of hair, alopecia, anesthesia of skin, chronic folliculitis, exacerbation of psoriasis, xerosis cutis; Autonomic—blurred vision, dry mouth; Thyroid Abnormalities—euthyroid goiter and/or hypothyroidism (including myxedema) with lower T_3 and T_4. I^{131} uptake may be elevated; EEG Changes—diffuse slowing, widening of the frequency spectrum, potentiation and disorganization of background rhythm; EKG Changes—reversible flattening, isoelectricity or inversion of T-waves; Miscellaneous—fatigue, lethargy, transient scotomata, dehydration, weight loss, tendency to sleep.

Reactions unrelated to dosage include: transient EEG and EKG changes, leukocytosis, headache, diffuse nontoxic goiter with or without hypothyroidism, transient hyperglycemia, generalized pruritus with or without rash, cutaneous ulcers, albuminuria, worsening of organic brain syndromes, excessive weight gain, edematous swelling of ankles or wrists, thirst or polyuria, sometimes resembling diabetes insipidus, and metallic taste. A single case of a syndrome resembling Raynaud's has been reported.

Dosage and Administration: *Acute Mania*—900 mg b.i.d. or 600 mg t.i.d. (1800 mg per day) usually will provide serum lithium levels ranging between 1.0 and 1.5 mEq/L. Serum levels should be determined twice per week until serum level and clinical condition have been stabilized.

Long-Term Control—900 mg to 1200 mg per day in two or three divided doses usually will maintain serum lithium levels at 0.6 to 1.2 mEq/L. Serum lithium levels should be monitored at least every two months.



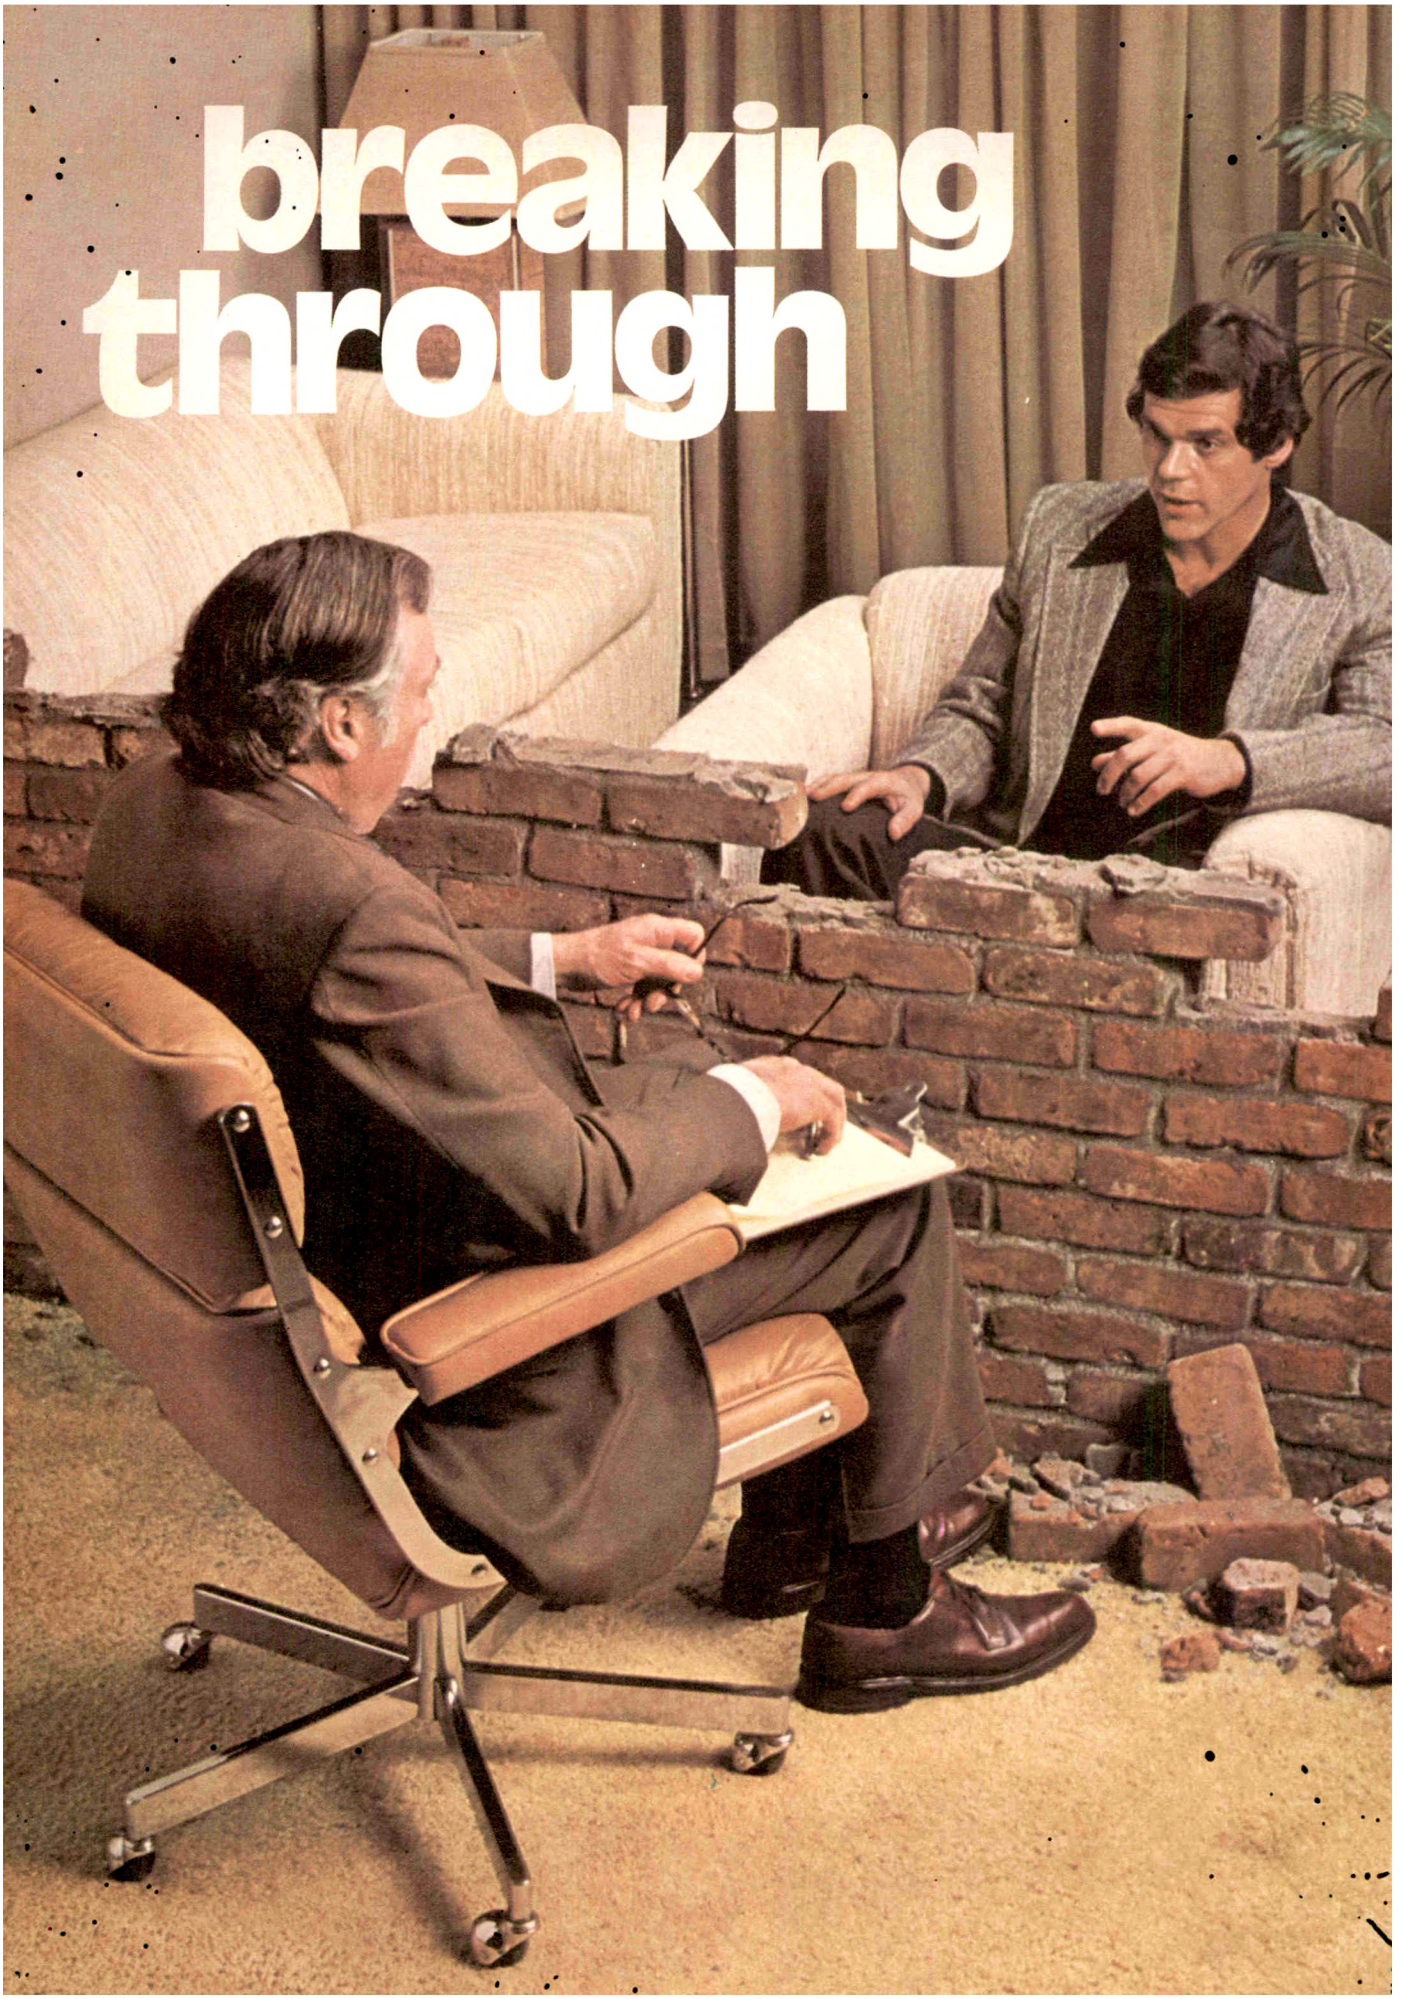
How Supplied: 300 mg peach-colored tablets, imprinted "ROWELL 7514" in red, are supplied in bottles of 100 and 1000.

ROWELL LABORATORIES, INC.
BAUDETTE, MINN. 56623

Do lithium dosage schedules keep your patients going around in circles?

Slow-Release Lithobid enables twice-a-day dosing as a practical route to better patient compliance. Patients on conventional lithium dosage forms can be converted to new Lithobid at the same daily dose, divided b.i.d. All patients on long-term lithium maintenance therapy will appreciate the convenience of this reduced dosage frequency.

Conventional tablets or capsules cause serum lithium spikes. New Lithobid blunts these peaks and keeps post-absorption serum levels within bounds.



Lithobid™
Slow-Release Lithium Carbonate 300 mg.

Now you can convert your lithium patients to this convenient, new b.i.d. dosage.

ROWELL®
LABORATORIES, INC.
BAUDETTE, MINN. 56623

Please see preceding page for brief summary of prescribing information.

1E May, 1979

breaking
through

In marked agitation with depression symptomatic relief may make the patient more accessible and responsive.

Rapid relief of marked agitation in many patients
The tranquilizer component alleviates symptoms of agitation and anxiety within a few days, without apparent dulling of mental acuity. Hypnotic effects from the tranquilizer component appear to be minimal, particularly in patients permitted to remain active. However, TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks.

Highly effective antidepressant action
The antidepressant component relieves symptoms of depression such as poor concentration and feelings of hopelessness as well as early morning awakening; adequate relief of symptoms may take a few weeks or even longer.

Helps break barriers to psychotherapy
As symptoms are relieved, many patients often communicate more effectively, become more cooperative, and are able to return to normal daily activities.

More prescribing convenience
There are now *five* tablet strengths of TRIAVIL for ease of dosage adjustment. For many patients with agitation and depression, you can now initiate therapy with one TRIAVIL® 4-50, containing 4 mg perphenazine and 50 mg amitriptyline HCl, b.i.d. The regimen is simple, economical, and may well enhance patient compliance.

Treatment with TRIAVIL—a balanced view:
TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to overdosage of other drugs or mask other disorders. The possibility of suicide in depressed patients remains until significant remission occurs. Such patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

For marked agitation with depression

dual-action **Triavil**®

containing perphenazine and amitriptyline HCl

MSD
MERCK SHARP & DOHME

Copyright © 1979 by Merck & Co., Inc.

Please see following page for a brief summary of prescribing information.

More dosage strengths than any other formulation containing a tranquilizer and an antidepressant

dual-action TRIAVIL®

containing perphenazine and amitriptyline HCl

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-50: Each tablet contains
4 mg perphenazine and 50 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides. There is sufficient experimental evidence to conclude that chronic administration of antipsychotic drugs which increase prolactin secretion has the potential to induce mammary neoplasms in rodents under the appropriate conditions. There are recognized differences in the physiological role of prolactin between rodents and humans. Since there are, at present, no adequate epidemiological studies, the relevance to human mammary cancer risk from prolonged exposure to perphenazine and other antipsychotic drugs is not known.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL, the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

PREVENTING MENTAL ILLNESS

Efforts and Attitudes

A new publication of The Joint Information Service of the American Psychiatric Association and the Mental Health Association

Raymond M. Glasscote; *Eleanor Kohn, Allan Beigel, Merrill F. Raber, Nancy Roeske, Bonnie A. Cox, James R. Raybin, Bernard L. Bloom*

There has long been interest in preventing mental illness, but no great emphasis on financing necessary research and pilot programs. Dramatic discoveries of nutritional, toxic, and infective causes of certain psychoses were made long ago and led to their prevention, but prevention of schizophrenia, mania, sociopathy, and biological depression, among other major disorders, requires further knowledge.

In recent years faith has grown that programs supporting those experiencing heavy stress and privation will provide benefits increasing the likelihood that they will remain functional, productive, and well. This volume provides a balanced, fairminded, and realistic explication of present possibilities and reasonable expectations. It explores a variety of viewpoints and describes in significant detail a variety of prevention-motivated programs for a variety of vulnerable people and provides such outcome information as is presently available.

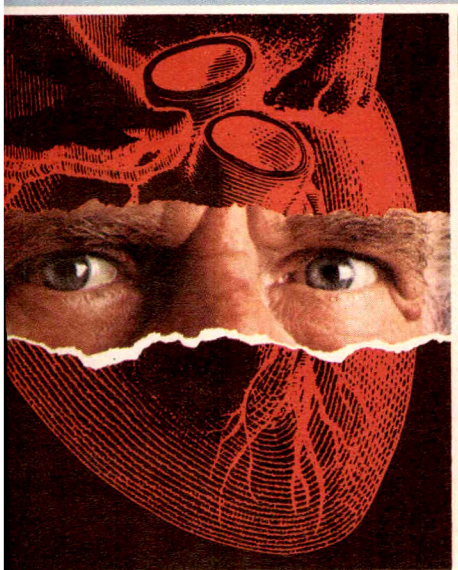
TM

Pharmacokinetics

Ativan (lorazepam) is eliminated more rapidly than other benzodiazepines; generates no clinically active metabolites. The half-life of free lorazepam is about 12 hours; steady-state blood levels are attained in 2-3 days. (Comparable data for diazepam: 20-50 hours and at least 7-10 days.) Ativan shows no evidence of accumulation, even when given in high doses for as long as 6 months. (The pharmacokinetic profile of a drug can define such characteristics as absorption, distribution, metabolism and elimination but cannot, at present, be directly related to its therapeutic effectiveness.)



Anxiety neuroses

In many nationwide studies involving thousands of patients with anxiety neuroses, Ativan (lorazepam) consistently provided significant relief of anxiety, tension, agitation and irritability as measured by standard Hamilton, Global (physician rated) and 35-Item (patient self-rated) scales.

Copyright © 1979, Wyeth Laboratories Div. of AHPC, N.Y., N.Y. All rights reserved.

They're all about the same, aren't they? Until recently, that seemed to sum up the prevalent attitude about the benzodiazepines. After all, they all work similarly and all are effective anxiolytics. With seven of these compounds now available, however, differences have begun to emerge. Foremost among them: different metabolic pathways, which distinguish the relatively short-acting Ativan (lorazepam) from long-acting diazepam, clorazepate and chlordiazepoxide. At the same time, your choice can be made with confidence in the clinical record of Ativan, which confirms its value in anxiety neuroses and in significant anxiety associated with functional or organic disorders, as well as in older patients.

Consider the record of Ativan:

Anxiety in cardiovascular disorders

Ativan (lorazepam) has been specifically evaluated and found effective in seven common protocol, double-blind studies involving 423 patients (211 on Ativan) whose anxiety was related to organic and functional cardiovascular disorders. The cardiovascular component has not, of course, been shown to be significantly benefited by such therapy.

Anxiety in gastrointestinal disorders

So far, nine common protocol, double-blind studies of Ativan have focused on anxious patients with functional or organic gastrointestinal complaints (457 patients, 234 on Ativan). Ativan was clearly effective in reducing the anxiety of these patients. The gastrointestinal component has not, of course, been shown to be significantly benefited by such therapy.

Anxiety in the aging patient

Because its simple metabolism is not readily impaired with advancing age, and accumulation is not likely to present a problem, Ativan is a good choice for older patients. Those who have trouble swallowing solid medication appreciate the small Ativan tablet, which is tasteless and disintegrates within seconds in water or fruit juice.

Ativan® (lorazepam) for Anxiety

See important information on following page.

Brief Summary of Prescribing Information

Indications and Usage: Symptomatic relief of anxiety, tension, agitation, irritability and insomnia associated with anxiety neuroses and transient situational disturbances; anxiety associated with depressive symptoms and as a treatment of symptoms of anxiety if such symptoms are a significant feature of functional or organic disorders, particularly gastrointestinal or cardiovascular.

Effectiveness in long-term use, i.e., more than 4 months, has not been assessed by systematic clinical studies. Reassess periodically usefulness of the drug for the individual patient.

Contraindications: Known sensitivity to benzodiazepines or acute narrow-angle glaucoma.

Warnings: Not recommended in primary depressive disorders or psychoses. As with all CNS-acting drugs, warn patients on lorazepam not to operate machinery or motor vehicles, and of diminished tolerance for alcohol and other CNS depressants.

Physical and Psychological Dependence: Withdrawal symptoms like those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepines (including convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Addiction-prone individuals, e.g. drug addicts and alcoholics, should be under careful surveillance when on benzodiazepines because of their predisposition to habituation and dependence. Withdrawal symptoms have also been reported following abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months.

Precautions: In depression accompanying anxiety, consider possibility for suicide.

For elderly or debilitated patients, initial daily dosage should not exceed 2mg to avoid oversedation.

Terminate dosage gradually since abrupt withdrawal of any antianxiety agent may result in symptoms like those being treated: anxiety, agitation, irritability, tension, insomnia and occasional convulsions.

Observe usual precautions with impaired renal or hepatic function.

Where gastrointestinal or cardiovascular disorders coexist with anxiety, note that lorazepam has not been shown of significant benefit in treating gastrointestinal or cardiovascular component.

Esophageal dilation occurred in rats treated with lorazepam for more than 1 year at 6mg/kg/day. No effect dose was 1.25mg/kg/day (approximately 6 times the maximum human therapeutic dose of 10mg/day). Effect was reversible only when treatment was withdrawn within 2 months of first observation. Clinical significance is unknown; but use of lorazepam for prolonged periods and in geriatric patients requires caution and frequent monitoring for symptoms of upper G.I. disease.

Safety and effectiveness in children under 12 years have not been established.

ESSENTIAL LABORATORY TESTS: Some patients have developed leukopenia; some have had elevations of LDH. As with other benzodiazepines, periodic blood counts and liver function tests are recommended during long-term therapy.

CLINICALLY SIGNIFICANT DRUG INTERACTIONS: Benzodiazepines produce CNS depressant effects when administered with such medications as barbiturates or alcohol.

CARCINOGENESIS AND MUTAGENESIS: No evidence of carcinogenic potential emerged in rats during an 18-month study. No studies regarding mutagenesis have been performed.

PREGNANCY: Reproductive studies were performed in mice, rats, and 2 strains of rabbits. Occasional anomalies (reduction of tarsals, tibia, metatarsals, malrotated limbs, gastroschisis, malformed skull and microphthalmia) were seen in drug-treated rabbits without relationship to dosage. Although all these anomalies were not present in the concurrent control group, they have been reported to occur randomly in historical controls. At 40mg/kg and higher, there was evidence of fetal resorption and increased fetal loss in rabbits which was not seen at lower doses. Clinical significance of these findings is not known. However, increased risk of congenital malformations associated with use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during first trimester of pregnancy has been suggested in several studies. Because use of these drugs is rarely a matter of urgency, use of lorazepam during this period should almost always be avoided. Possibility that a woman of child-bearing potential may be pregnant at institution of therapy should be considered. Advise patients if they become pregnant to communicate with their physician about desirability of discontinuing the drug.

In humans, blood levels from umbilical cord blood indicate placental transfer of lorazepam and its glucuronide.

NURSING MOTHERS: It is not known if oral lorazepam is excreted in human milk like other benzodiazepines. As a general rule, nursing should not be undertaken while on a drug since many drugs are excreted in milk.

Adverse Reactions, if they occur, are usually observed at beginning of therapy and generally disappear on continued medication or on decreasing dose. In a sample of about 3,500 anxious patients, most frequent adverse reaction is sedation (15.9%), followed by dizziness (6.9%), weakness (4.2%) and unsteadiness (3.4%). Less frequent are disorientation, depression, nausea, change in appetite, headache, sleep disturbance, agitation, dermatological symptoms, eye function disturbance, various gastrointestinal symptoms and autonomic manifestations. Incidence of sedation and unsteadiness increased with age. Small decreases in blood pressure have been noted but are not clinically significant, probably being related to relief of anxiety.

Overdosage: In management of overdosage with any drug, bear in mind that multiple agents may have been taken. Manifestations of overdosage include somnolence, confusion and coma. Induce vomiting and/or undertake gastric lavage followed by general supportive care, monitoring of vital signs and close observation. Hypotension, though unlikely, usually may be controlled with Levarterenol Bitartrate Injection U.S.P. Usefulness of dialysis has not been determined.

Ativan®(IV) for Anxiety
(lorazepam)

Dosage: **Individualize for maximum beneficial effects. Increase dose gradually when needed, giving higher evening dose before increasing daytime doses. Anxiety, usually 2-3mg/day given b.i.d. or t.i.d.; dosage may vary from 1 to 10mg/day in divided doses. For elderly or debilitated, initially 1-2mg/day; insomnia due to anxiety or transient situational stress, 2-4mg h.s.**

How Supplied: **0.5, 1.0 and 2.0mg tablets.**

SURVEY OF PSYCHIATRY

This *new* 16-hour program offers a fresh, comprehensive overview of psychiatric theory, practice, and research. Authored by a distinguished faculty, specialists in their field, SURVEY OF PSYCHIATRY presents *completely new,* up-to-date information for the practicing physician who wants to keep abreast of the current state of the art, and may assist for certifying exams (such as the American Board of Psychiatry and Neurology).

Course Director:
Shervert H. Frazier, MD.
Psychiatrist-in-Chief
McLean Hospital Professor of Psychiatry
Harvard Medical School

SURVEY OF PSYCHIATRY has been designed to meet the needs of the busy physician.

- Versatile programs — ideal for home study, teaching, seminars, group study, and refresher courses
- Maximum educational and review benefits in easy-to-use format
- Convenient, flexible — no time spent away from practice

Course Components:

- Audiocassettes — 14 live lectures on 14 audiocassettes
- Course Syllabus (94 pages) — fully illustrated with tables, charts and slide reproductions, plus a concise bibliography for further study
- Test Section — questions and computerized test sheet with self-addressed mailing envelope for registrants desiring Continuing Medical Education Category I credits

Credit Statement:
As an organization accredited by the Liaison Committee on Continuing Medical Education (LCCME) to provide continuing medical education, the American Psychiatric Association certifies that this continuing medical education offering meets the criteria for up to 16 hours of LCCME Category I CME credit, provided it is used and completed as designed.

Order Form

SURROUNDED BY A WALL OF INDIFFERENCE

'STELAZINE' HELPS FIND A WAY THROUGH

The schizophrenic patient is often withdrawn, aloof and emotionally unresponsive. For such patients, 'Stelazine' provides effective, unsurpassed control of these and other psychotic symptoms.

Also important, 'Stelazine' can help patients participate in your therapeutic programs. 'Stelazine' usually does not cause excessive sedation and offers the convenience of b.i.d. dosage.

In fact, no other antipsychotic agent has demonstrated significantly greater overall effectiveness and significantly fewer adverse effects than 'Stelazine'.

'Stelazine'. A first choice for therapy.

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Generally avoid using in patients hypersensitive (e.g., blood dyscrasias, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Additive effect is possible with other C.N.S. depressants, including alcohol.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions, peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

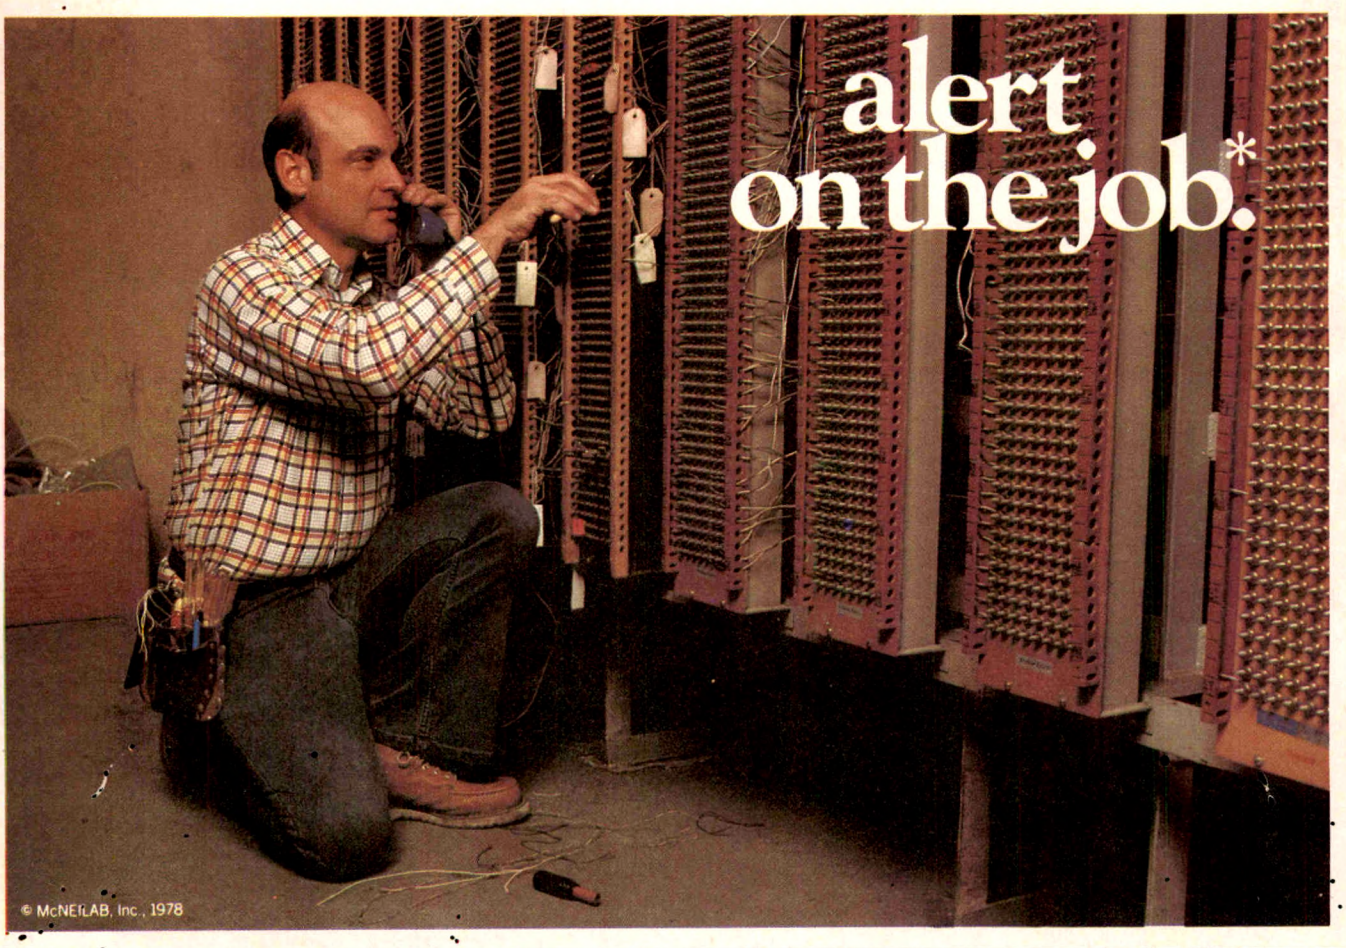
TABLETS: 5 and 10 mg.



brand of

TRIFLUOPERAZINE HCl

A First Choice for Therapy

Responsive to therapy...

alert on the job.*

Haldol®
(haloperidol)
tablets/concentrate/injection

For long-term management of psychotic patients... with minimal risk of adverse effects

Highly effective in a wide range of acute and chronic psychotic disorders[1-7]

Permits aggressive titration to effective dosage levels for optimal control[1,4]

Usually leaves patients alert and responsive...
easier to reach with supportive measures[1-3]

*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Minimal risk of hypotension, oversedation, or troublesome anticholinergic effects[3-5,7-9]
Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. Although some instances of drowsiness have been reported, marked sedation is rare.

Common side effects easily controlled[1,3-7]
Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

HALDOL® (haloperidol)

tablets/concentrate/injection

A dosage form for every therapeutic need

Summary of Prescribing Information

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use With Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn.

Persistent Tardive Dyskinesia: Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent.

Other CNS Effects: Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms.

Cardiovascular Effects: Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

Caution: Federal law prohibits dispensing without prescription.

Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646.

* haloperidol present as the lactate

THE CHRONIC MENTAL PATIENT

Report of a Conference held in January 1978
Edited by
John A. Talbott, M.D.

with contributions by James T. Barter, M.D., Paul R. Friedman, J.D., Raymond Glasscote, M.A., Trevor D. Glenn, M.D., Norman V. Lourie, M.S.W., W. Walter Menninger, M.D., Arthur T. Meyerson, M.D., Kenneth Minkoff, M.D., Samuel Muszynski, M.S.W., Lucy D. Ozarin, M.D., Gordon L. Paul, Ph.D., Ronald Peterson, Steven S. Sharfstein, M.D., Judith Clark Turner, Jane Bloom Yohalem, J.D.

This 277-page Report of the Conference, sponsored by APA and President Carter's Commission on Mental Health, identifies the chronic mental patient population, spells out where they are and what their needs and rights are. It specifies what programs work and what programs do not work in meeting the needs of these patients. It elaborates on the obstacles to implementing effective programs and the economic issues involved. It delineates the pros and cons of case management and specifies responsibility for coordinating, implementing, and monitoring services to chronic mental patients.

Finally, it proposes a *Call to Action* which opens with this statement: "There is no more urgent concern than the needs of the chronic mentally ill who suffer from severe, persistent, or recurrent mental illnesses with residual social and vocational disabilities. As a result of the deinstitutionalization programs of the past decade and the continuing growth of high risk populations that generate chronically ill, the problems associated with the care of these patients constitute a national crisis."

Since the Conference, the APA Assembly and the Board of Trustees have both approved the "Call to Action" which calls upon the APA to take the lead in undertaking programs to elevate the prestige and value of work with chronic mentally ill patients.

It follows that all APA members should be thoroughly versed in the current problems of this chronic patient population. This is best accomplished by reading this Conference Report now available from APA Publications Services at $11.00 a copy.

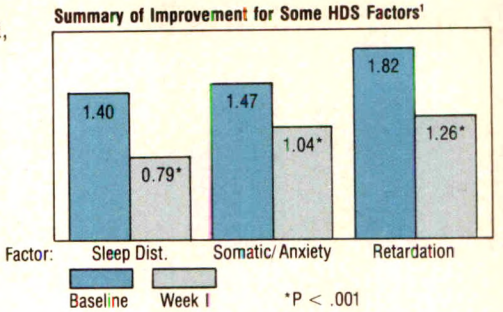
HCP

When depressive symptoms come in a cluster of blues...



Adapin® (doxepin HCl) helps patients see life in all its colors

Improvements noted at one week

Depressed patients often present with fatigue, anorexia, anxiety, mood swings, loss of interest, *and most frequently, early awakening and insomnia*. In a summation of 9 clinical studies involving 198 patients, significant clinical improvement was noted after the first week of doxepin treatment.[1] However, optimal antidepressant response may not be evident for two to three weeks.

Summary of Improvement for Some HDS Factors[1]

Normalized sleep patterns

In a study of clinically depressed patients with symptoms of insomnia, treatment with doxepin significantly reduced difficulty falling asleep, difficulty staying asleep and frequency of early morning awakening.[2]

Low potential for cardiotoxicity

The incidence of tachycardia and hypotension, which have been observed during treatment with tricyclic antidepressants, has been reported infrequently with doxepin. In 452 patients given doxepin, the incidence of tachycardia was 2.88%; in 495 patients, the incidence of hypotension was 2.62%.[3]

Now available...New 75 mg capsules for h.s. dosage

Brief Summary of Prescribing Information ADAPIN® (doxepin HCl) Capsules
Indications–Relief of symptoms of anxiety and depression.
Contraindications–Glaucoma, tendency toward urinary retention or hypersensitivity to doxepin.
Warnings–Adapin has not been evaluated for safety in pregnancy. No evidence of harm to the animal fetus has been shown in reproductive studies. There are no data concerning secretion in human milk, nor on effect in nursing infants.

Usage in children under 12 years of age is not recommended. MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug, as serious side-effects and death have been reported with the concomitant use of certain drugs and MAO inhibitors.

In patients who may use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage.

Precautions–Drowsiness may occur and patients should be cautioned against driving a motor vehicle or operating hazardous machinery. Since suicide is an inherent risk in depressed patients they should be closely supervised while receiving treatment. Although Adapin has shown effective tranquilizing activity, the possibility of activating or unmasking latent psychotic symptoms should be kept in mind. This product contains FD&C Yellow No. 5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. Although the overall incidence of FD&C Yellow No. 5 (tartrazine) sensitivity in the general population is low, it is frequently seen in patients who also have aspirin hypersensitivity.

Adverse Reactions–Dry mouth, blurred vision and constipation have been reported. Drowsiness has also been observed.

Adverse effects occurring infrequently include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as sweating, tachycardia and hypotension. Weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash and pruritus may also occur.

Dosage and Administration–In mild to moderate anxiety and/or depression: 25 mg t.i.d. Increase or decrease the dosage according to individual response. Daily dosage, up to 150 mg may be taken at bedtime without loss of effectiveness. Usual optimum daily dosage is 75 mg to 150 mg per day not to exceed 300 mg per day.

Antianxiety effect usually precedes the antidepressant effect by two or three weeks.

How Supplied–Each capsule contains doxepin, as the hydrochloride. 10 mg, 25 mg, 50 mg, 75 mg and 100 mg capsules in bottles of 100 and 1000.

For complete prescribing information please see package insert or PDR.

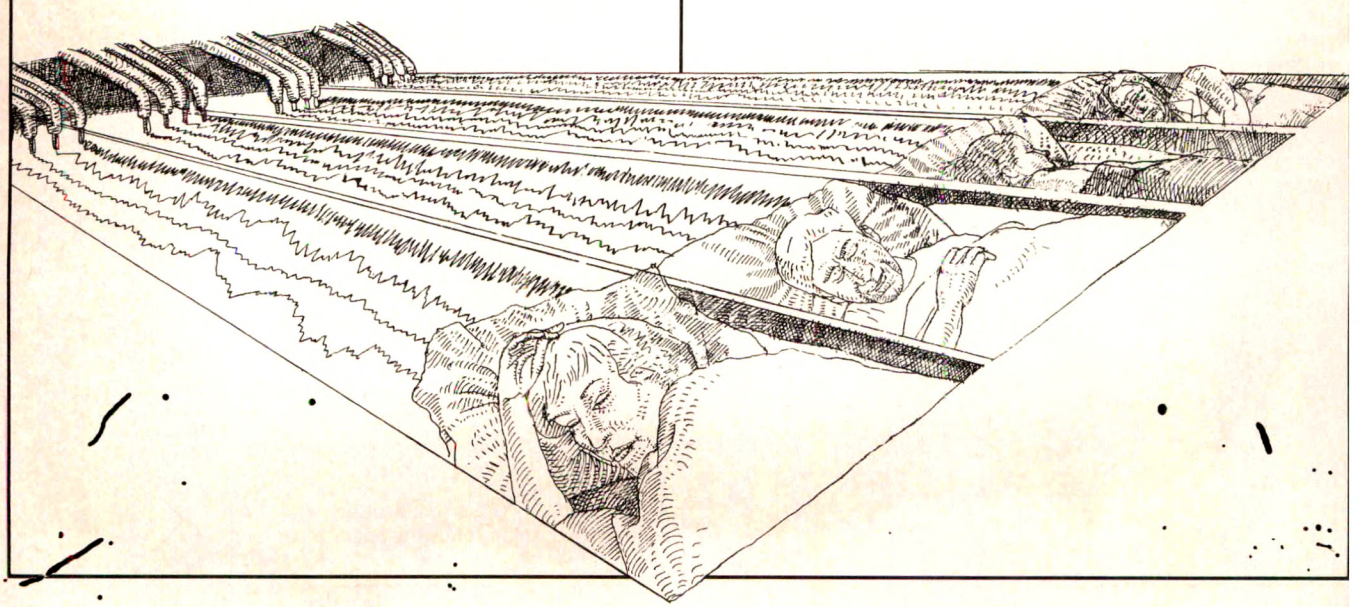
Adapin® (doxepin HCl) ... effective single-entity drug with antidepressant and antianxiety effects

A-252

DALMAN
(flurazepam HCl/Roch

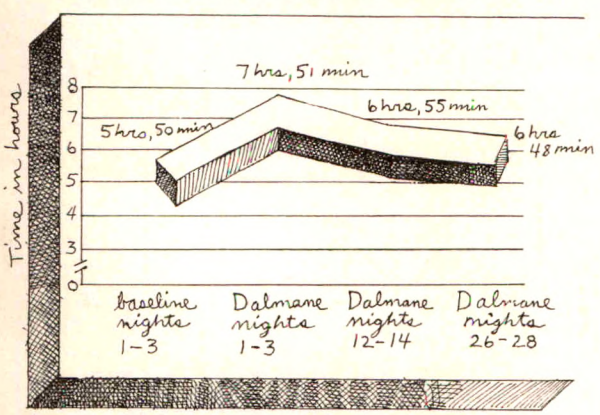


MORE POLYGRAPHIC EVIDENC

Sleep research laboratory testing of insomnia patients for 995 subject nights demonstrates efficacy of Dalmane (flurazepam HCl/Roche)[1]

In 14 separate studies, subjects given Dalmane were monitored with polygraphic recordings for a total of 995 nights, objectively demonstrating the efficacy of Dalmane.

Efficacy from the first night through 28 nights, without need to increase dosage



Dalmane (flurazepam HCl/Roche) is the only sleep medication objectively proven effective through 28 consecutive nights of administration in two separate studies in the sleep research laboratory.[2-4] The prolonged use of Dalmane is seldom necessary; should it be, appropriate patient evaluations such as periodic blood counts and liver and kidney function tests are recommended.

OFFERS

OF EFFICACY FOR INSOMNIA

Dalmane® (flurazepam HCl/Roche) improved sleep during short, intermediate and longer-term use

Improvement shown represents mean improvement, in hours, of total sleep time. n=5

Adapted from Dement WC, *et al: Behav Med* 5:25-31, Oct 1978

Since most insomnia is transitory in nature, initiate therapy at the lowest effective dose for the shortest time advisable to achieve a predetermined therapeutic goal.

References:
1. Data on file, Medical Department, Hoffmann-La Roche Inc., Nutley NJ
2. Kales A, *et al: Clin Pharmacol Ther 19:* 576-583, May 1976

4. Kales A, *et al: Clin Pharmacol Ther 18:* 356-363, Sep 1975

Clinical documentation of efficacy in 4950 patients with insomnia[1]

Dalmane (flurazepam HCl/Roche) efficacy was evaluated in 18 clinical studies. These included paired-night, double-blind crossover, double-blind comparison and patient preference studies. Results of these studies demonstrated and confirmed the effectiveness of Dalmane.

Periodic evaluation of patient's sleep habits may help prevent subsequent insomnia

Should insomnia recur, the patient may need guidance in setting up a regular sleep program. This may include establishment of a regular bedtime hour, taking a warm bath prior to retiring and avoidance of alcohol, stimulants or heavy meals late in the evening.

DALMANE® (IV)

flurazepam HCl/Roche
15-mg and 30-mg capsules

UNMATCHED PROOF, UNMATCHED EFFICACY

Please see summary of product information on following page.

ROCHE®

Protocol for insomnia management

☐ Treat physical and/or psychological factors that may underlie an inability to sleep.

☐ Thoroughly question and evaluate new patients who specifically request sleep medications.

☐ Consider other medications the patient may be taking (including alcoholic beverages) and be aware of possible drug interactions.

☐ Select a sleep medication with objectively *documented* proof of efficacy and a wide margin of safety.

☐ Initiate treatment at the lowest effective dose for the period of time deemed necessary *to achieve a reasonable therapeutic goal.*

☐ Monitor response to therapy and, based upon patient reassessment, determine need for continuing medication on an individual basis.

☐ Advise patients who ingest alcoholic beverages or other CNS depressants against doing so while on sleep medication. CNS stimulants such as caffeine should also be discontinued.

☐ Caution patients against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving a motor vehicle shortly after ingesting the drug. In addition, as with all CNS depressants, patients may have reduced motor performance while on hypnotic therapy and should be advised accordingly.

☐ Avoid prescribing for suicidal or dependency-prone individuals whose histories indicate an inability to handle any psychoactive substances including alcohol.

Now available from Roche—important guidance for your patients with insomnia.

DALMANE® (IV)
flurazepam HCl/Roche

One 15-mg capsule *h.s.*—recommended initial dosage for elderly or debilitated patients.
One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Objective sleep laboratory data have shown effectiveness for at least 28 consecutive nights of administration. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).
Usage in Pregnancy: **Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane, a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**
Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated patients, it is recommended that the dosage be limited to 15 mg to reduce risk of oversedation, dizziness, confusion and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies, or with impaired renal or hepatic function. Periodic blood counts and liver and kidney function tests are advised during repeated therapy.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect.
Adults: 30 mg usual dosage; 15 mg may suffice in some patients.
Elderly or debilitated patients: 15 mg recommended initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

ROCHE PRODUCTS INC.
Manati, Puerto Rico 00701

ROCHE®

Alberta, Canada's fourth largest province, is experiencing unique economic growth based upon energy resource wealth, complemented by a commitment to the future and an enhancement of the quality of life for its citizens. In medicine and health care, this commitment is evident in support to universities, emphasis on medical research, and investment in facilities and services aimed at health care.

Alberta Hospital Edmonton is a progressive, active treatment psychiatric hospital comprised of acute, geriatric, rehabilitation, and forensic treatment services. The centre provides 120 beds for acute psychiatric admissions, and will be opening an expanded new forensic facility in late 1981. Fostering a multidisciplinary approach, Alberta Hospital Edmonton promotes progressive treatment methods and encourages active clinical and applied research.

FORENSIC AND CLINICAL PSYCHIATRISTS

prepared to accept the opportunity to practise in this vigorous, progressive environment, who hold F.R.C.P.(C), M.R.C. (PSYCH.) or equivalent are invited to forward Curriculum Vitae to:

Dr. David R. Cornish

PSYCHIATRIST

CERTIFIED

Professor (for position of Associate/or higher depending on qualifications.)

Must be native Arabic-speaker, with work experience in Arab countries. Preferably with strong background in research and/or clinical psychiatry.

Duties will include teaching research courses in newly established department and work in Public Health Clinic.

Benefits: separate housing allowance, furniture allowance, insurance coverage for self and family (up to four children under the age of eighteen), tickets to return home (place of recruitment) for self and family for annual vacation, two months bonus salary for each year of service, annual raise.

Salary, negotiable, depending on qualifications.

There are several positions available immediately. Send resume and certified copies of school and professional documents to: University of Garyounis in Benghazi, People's Bureau of The Socialist People's Libyan Arab Jamahiriya, Cultural Section, Post Office Box 19125, Washington, D.C. 20036.

DALHOUSIE UNIVERSITY
DEPARTMENT OF PSYCHIATRY

Chief of Service : Saint John Regional Hospital

The Saint John Regional Hospital, a teaching hospital of the Faculty of Medicine, Dalhousie University, is inviting applications from qualified medical practitioners for the position of Chief of the Department of Psychiatry.

A new 700-bed hospital with capacity to expand to 800 beds plus is completing construction to replace the present Regional Hospital in April 1982.

The Psychiatry facilities will include an expanded 58 bed in-patient unit and a new Day Ambulatory Care Unit.

The successful applicant will work closely with Dalhousie University and Centracare, a 500-bed Psychiatric facility in Saint John to plan and co-ordinate and organize a wide scope of Psychiatric services including Forensic, Pediatric and Adolescent Units.

The hospital is integrated with Dalhousie University for Resident and Interne Training. The Chief of Psychiatry will be appointed to an appropriate rank in the Faculty of Medicine.

The terms of employment are clearly competitive and can consider such areas as resettlement incentive and part-time private practice.

The residential environs of Saint John are most attractive, with a full range of educational (including University) and recreational facilities — golf, curling, skiing, sailing etc.

Submit applications with complete curriculum vitae to:

Chairman of Selection Advisory Committee
Department of Psychiatry — Dalhousie University
c/o The Dean's Office (New Brunswick)
P.O. Box 2100
Saint John, New Brunswick, Canada.
E2L 4L2.

CHILD AND ADOLESCENT PSYCHIATRIST

Child, Adolescent & Family Psychiatric Services
South Australia.

Willis House Adolescent Unit, Adelaide.

APPLICATIONS ARE INVITED FOR THE POSITION OF: — SENIOR PSYCHIATRIST-IN-CHARGE, MO8

$37,207.

The South Australian Health Commission is promoting the development of existing services in Child, Adolescent and Family Psychiatry in South Australia.

Opportunities exist for career psychiatrists in this field.

Willis House is the adolescent component of the Child, Adolescent and Family Psychiatric Services. The facility provides comprehensive diagnostic and therapeutic and educational services for in-patients, day patients and out patient adolescents and their families.

The position requires that candidates be well trained, adolescent and family psychiatrists with a firm clinical base. Skills in teaching, staff development, consultation and liaison work with a major emphasis on leadership are essential.

Qualifications and Experience:

1. Eligible for Membership of Royal Australian & New Zealand College of Psychiatrists.
2. Child Psychiatry (College accred.)
3. Minimum of 4 years experience since qualification, at least 2 of which should have been spent in C.A.F.P.S. is desirable.
4. Experience in clinical administration and staff management is a recommendation.

Enquiries:

Dr. C. Irwin,
Director,
Child, Adolescent and Family
Psychiatric Services.
Telephone (08) 223-2022.

Applications:

Applications are invited from persons regardless of sex, race, ethnic background or physical impairment. The names of 3 referees and curriculum vitae, should be forwarded and applications addressed to:

Manager,
Personnel Services,
South Australian Health
Commission,
52 Pirie Street,
ADELAIDE. 5000
South Australia.
Telephone (08) 228 0317.

Brief Summary of Prescribing Information

Indications and Usage: Symptomatic relief of anxiety, tension, agitation, irritability and insomnia associated with anxiety neuroses and transient situational disturbances; anxiety associated with depressive symptoms and as a treatment of symptoms of anxiety if such symptoms are a significant feature of functional or organic disorders, particularly gastrointestinal or cardiovascular.

Effectiveness in long-term use, i.e., more than 4 months, has not been assessed by systematic clinical studies. Reassess periodically usefulness of the drug for the individual patient.

Contraindications: Known sensitivity to benzodiazepines or acute narrow-angle glaucoma.

Warnings: Not recommended in primary depressive disorders or psychoses. As with all CNS-acting drugs, warn patients on lorazepam not to operate machinery or motor vehicles, and of diminished tolerance for alcohol and other CNS depressants.

Physical and Psychological Dependence: Withdrawal symptoms like those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepines (including convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Addiction-prone individuals, e.g. drug addicts and alcoholics, should be under careful surveillance when on benzodiazepines because of their predisposition to habituation and dependence. Withdrawal symptoms have also been reported following abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months.

Precautions: In depression accompanying anxiety, consider possibility for suicide.

For elderly or debilitated patients, initial daily dosage should not exceed 2mg to avoid oversedation.

Terminate dosage gradually since abrupt withdrawal of any antianxiety agent may result in symptoms like those being treated: anxiety, agitation, irritability, tension, insomnia and occasional convulsions.

Observe usual precautions with impaired renal or hepatic function.

Where gastrointestinal or cardiovascular disorders coexist with anxiety, note that lorazepam has not been shown of significant benefit in treating gastrointestinal or cardiovascular component.

Esophageal dilation occurred in rats treated with lorazepam for more than 1 year at 6mg kg day. No effect dose was 1.25mg/kg/day (approximately 6 times the maximum human therapeutic dose of 10mg/day). Effect was reversible only when treatment was withdrawn within 2 months of first observation. Clinical significance is unknown; but use of lorazepam for prolonged periods and in geriatric patients requires caution and frequent monitoring for symptoms of upper G.I. disease.

Safety and effectiveness in children under 12 years have not been established.

ESSENTIAL LABORATORY TESTS: Some patients have developed leukopenia; some have had elevations of LDH. As with other benzodiazepines, periodic blood counts and liver function tests are recommended during long-term therapy.

CLINICALLY SIGNIFICANT DRUG INTERACTIONS: Benzodiazepines produce CNS depressant effects when administered with such medications as barbiturates or alcohol.

CARCINOGENESIS AND MUTAGENESIS: No evidence of carcinogenic potential emerged in rats during an 18-month study. No studies regarding mutagenesis have been performed.

PREGNANCY: Reproductive studies were performed in mice, rats, and 2 strains of rabbits. Occasional anomalies (reduction of tarsals, tibia, metatarsals, malrotated limbs, gastroschisis, malformed skull and microphthalmia) were seen in drug-treated rabbits without relationship to dosage. Although all these anomalies were not present in the concurrent control group, they have been reported to occur randomly in historical controls. At 40mg/kg and higher, there was evidence of fetal resorption and increased fetal loss in rabbits which was not seen at lower doses. Clinical significance of these findings is not known. However, increased risk of congenital malformations associated with use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during first trimester of pregnancy has been suggested in several studies. Because use of these drugs is rarely a matter of urgency, use of lorazepam during this period should almost always be avoided. Possibility that a woman of child-bearing potential may be pregnant at institution of therapy should be considered. Advise patients if they become pregnant to communicate with their physician about desirability of discontinuing the drug.

In humans, blood levels from umbilical cord blood indicate placental transfer of lorazepam and its glucuronide.

NURSING MOTHERS: It is not known if oral lorazepam is excreted in human milk like other benzodiazepines. As a general rule, nursing should not be undertaken while on a drug since many drugs are excreted in milk.

Adverse Reactions, if they occur, are usually observed at beginning of therapy and generally disappear on continued medication or on decreasing dose. In a sample of about 3,500 anxious patients, most frequent adverse reaction is sedation (15.9%), followed by dizziness (6.9%), weakness (4.2%) and unsteadiness (3.4%). Less frequent are disorientation, depression, nausea, change in appetite, headache, sleep disturbance, agitation, dermatological symptoms, eye function disturbance, various gastrointestinal symptoms and autonomic manifestations. Incidence of sedation and unsteadiness increased with age. Small decreases in blood pressure have been noted but are not clinically significant, probably being related to relief of anxiety.

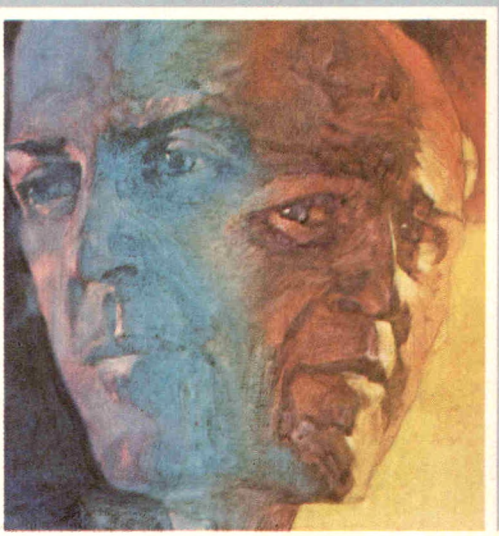
Overdosage: In management of overdosage with any drug, bear in mind that multiple agents may have been taken. Manifestations of overdosage include somnolence, confusion and coma. Induce vomiting and/or undertake gastric lavage followed by general supportive care, monitoring of vital signs and close observation. Hypotension, though unlikely, usually may be controlled with Levarterenol Bitartrate Injection U.S.P. Usefulness of dialysis has not been determined.

Ativan® IV for Anxiety
(lorazepam)

Dosage: **Individualize for maximum beneficial effects. Increase dose gradually when needed, giving higher evening dose before increasing daytime doses. Anxiety, usually 2-3mg/day given b.i.d. or t.i.d.; dosage may vary from 1 to 10mg/day in divided doses. For elderly or debilitated, initially 1-2mg/day; insomnia due to anxiety or transient situational stress, 2-4mg h.s.**

How Supplied: **0.5, 1.0 and 2.0mg tablets.**

Wyeth Laboratories
Philadelphia, PA 19101

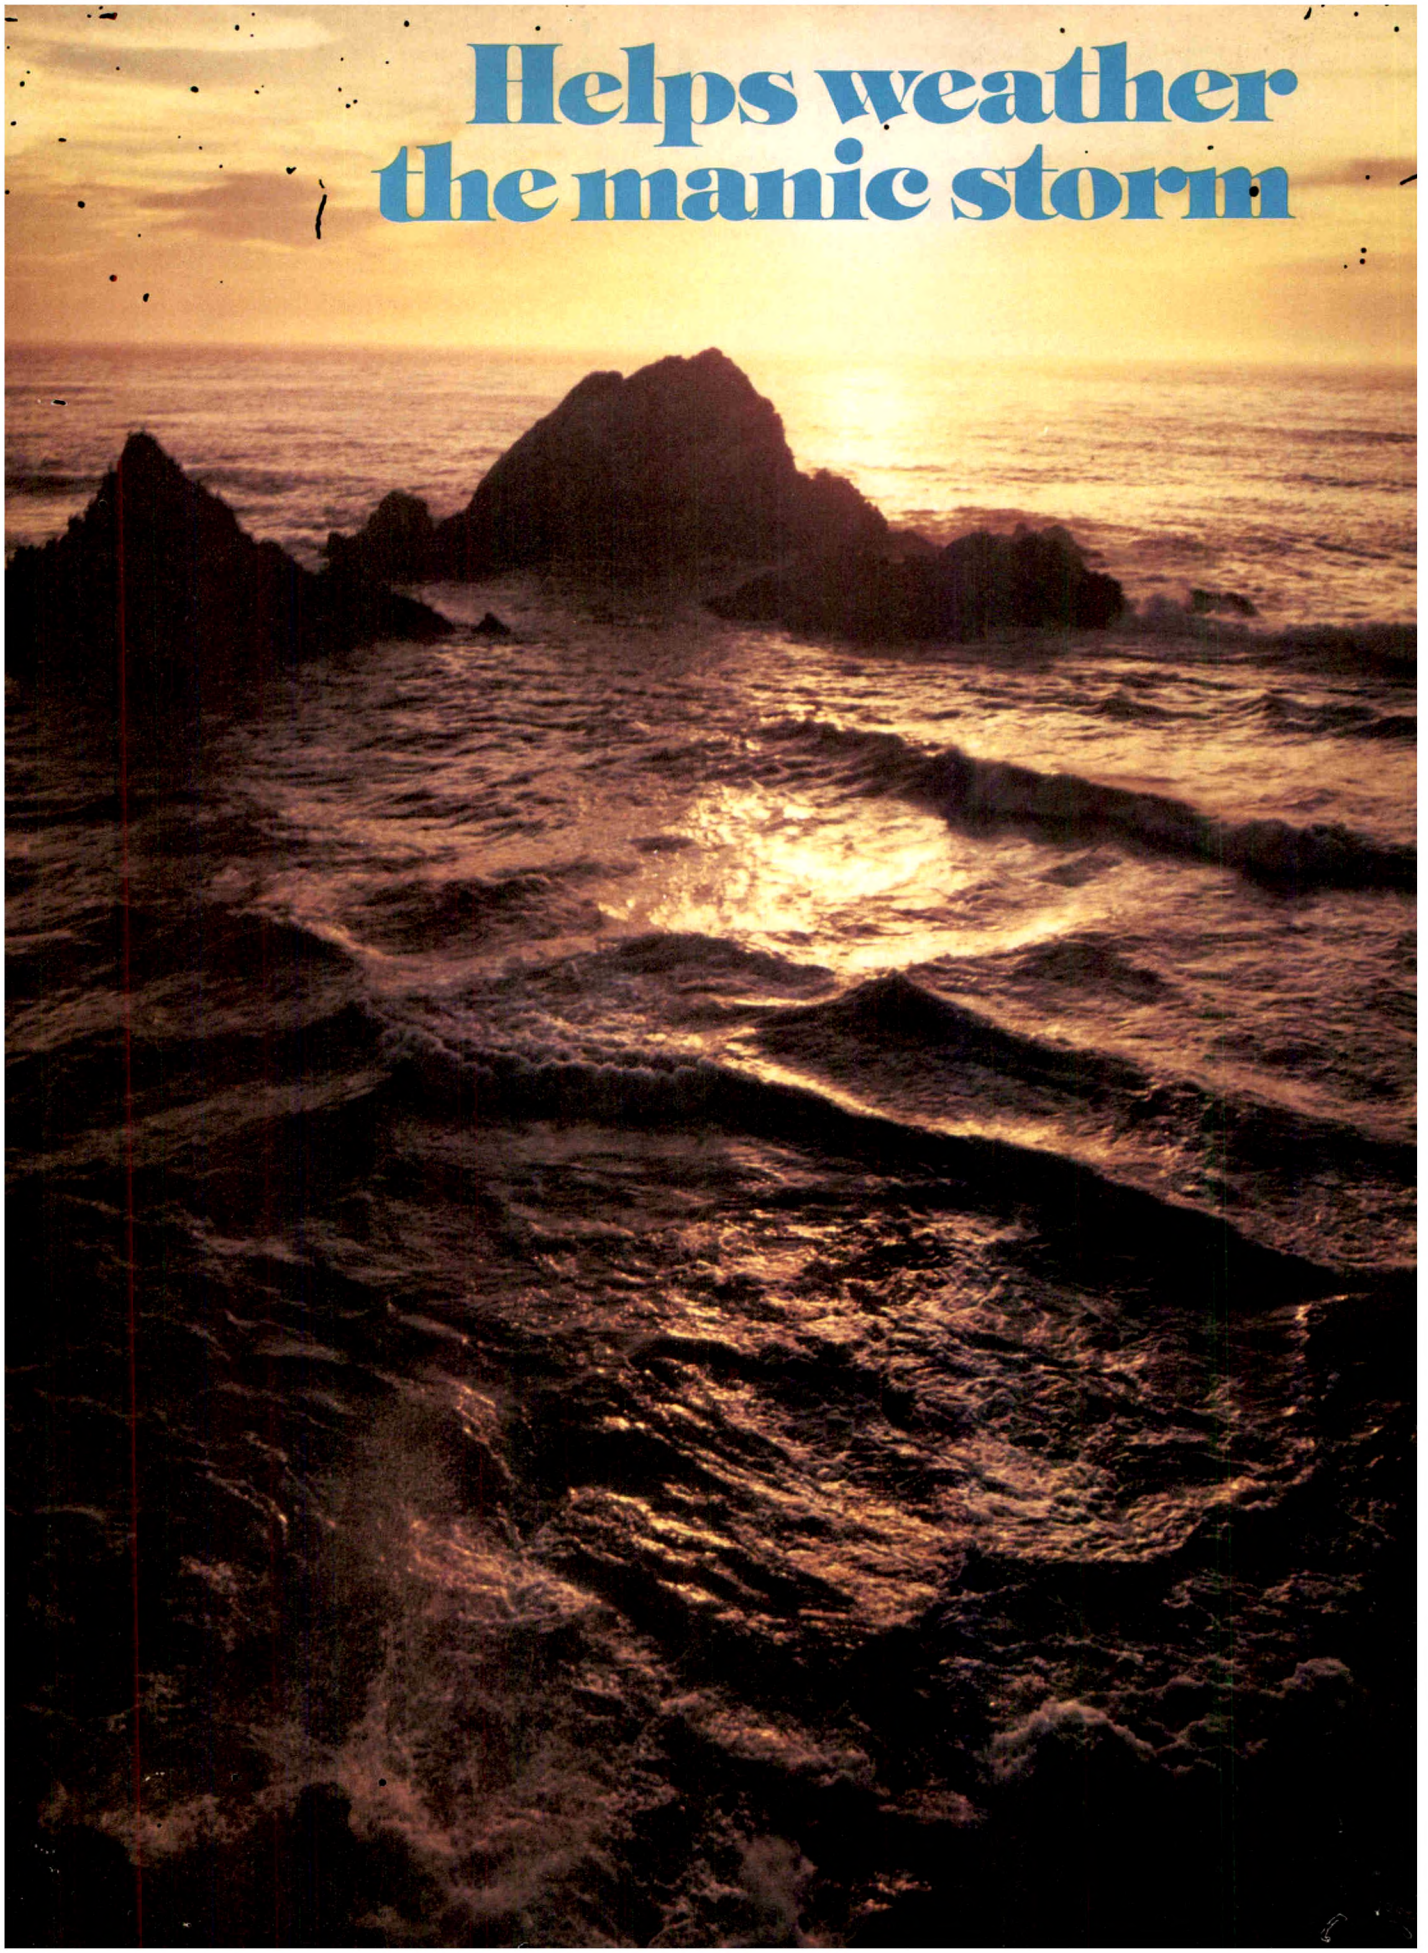


Copyright © 1979, Wyeth Laboratories
Div. of AHPC, N.Y., N.Y. All rights reserved.

A mixed syndrome. When drug intervention is indicated in patients whose anxiety is accompanied by depressive symptoms, the choice, essentially, is among three basic strategies: (1) an antidepressant; (2) a tranquilizer; (3) a combination of (1) and (2).

With respect to strategy (2), you should know that Ativan (lorazepam) has been shown to be statistically and clinically significantly effective in alleviating the anxiety component of this mixed syndrome, in common protocol controlled studies of 653 patients (337 on Ativan).

Since Ativan was also found to be compatible with tricyclics, if you opt for strategy (3), your patient has the benefit of rapid anxiolytic action, absence of long-acting metabolites and rapid clearance when you decide to discontinue Ativan. All benzodiazepines, however, including Ativan, produce added CNS depressant effects when administered with alcohol and other CNS depressants.



In either case, Ativan offers you the convenience of a b.i.d. schedule and a flexibility not possible with any fixed combination.

See important information on preceding page.

Ativan® (IV) for (lorazepam) Anxiety

associated with depressive symptoms

Helps weather
the manic storm

maintenance therapy with Eskalith®

brand of

lithium carbonate

300 mg capsules and
300 mg scored tablets

In manic-depressive patients with a history of mania, 'Eskalith'

- prevents or diminishes the intensity of future episodes
- can increase the intervals between episodes
- helps patients function within normal limits

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

> **WARNING**
> Lithium toxicity is closely related to serum lithium levels, and can occur at doses close to therapeutic levels. Facilities for prompt and accurate serum lithium determinations should be available before initiating therapy.

INDICATIONS: Treatment of manic episodes of manic-depressive illness. Maintenance therapy prevents or diminishes the intensity of subsequent episodes in manic-depressive patients with a history of mania.

WARNINGS: Lithium should generally not be given to patients with significant renal or cardiovascular disease, severe debilitation or dehydration, sodium depletion, or to patients receiving diuretics.

Lithium may prolong the effects of neuromuscular blocking agents. Such agents should be given with caution to patients receiving lithium. Lithium therapy has been reported in some cases to be associated with morphologic changes in the kidneys. The relationship between such changes and renal function has not been established.

Caution patient and family to watch for diarrhea, vomiting, tremor, mild ataxia, drowsiness, or muscular weakness as signs of lithium toxicity, and to discontinue therapy and contact a physician should they occur. Patients receiving combined therapy with lithium and an antipsychotic should be monitored closely for early evidence of neurologic toxicity and treatment discontinued promptly if such signs appear. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery).

Lithium should not be used in pregnancy, especially during the first trimester, unless potential benefits outweigh possible hazards. Except in rare and unusual circumstances, nursing should not be undertaken while a patient is on lithium therapy, since lithium is excreted in human milk.

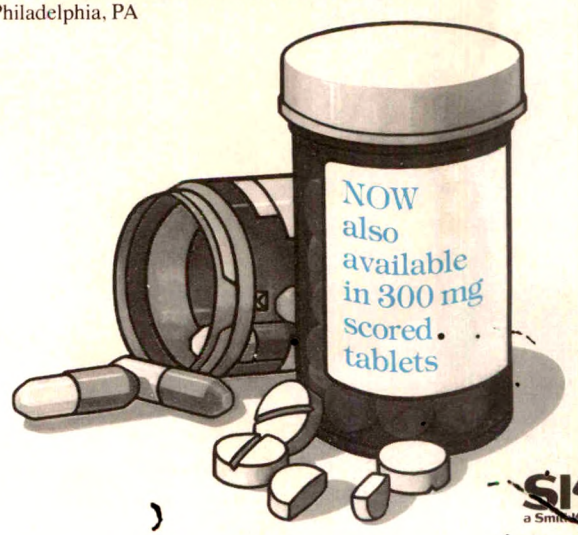
Not recommended for children under 12.

PRECAUTIONS: Lithium tolerance is greater during the acute manic phase and decreases when manic symptoms subside.

Lithium therapy may lead to sodium depletion. Normal diet (including salt) and adequate fluid intake (2500-3000 ml.) must be maintained, at least during initial stabilization period. Protracted sweating or diarrhea can decrease tolerance; in such cases, administer supplemental fluid and salt.

Sweating, diarrhea, and concomitant infection with elevated temperatures may require temporary reduction or cessation of dosage.

Where hypothyroidism exists, thyroid function should be monitored during lithium stabilization and maintenance; where hypothyroidism occurs during stabilization and maintenance, supplemental thyroid treatment may be used.



ADVERSE REACTIONS: Mild to moderate toxic reactions may occur at serum lithium levels from 1.5 to 2.5 mEq./1., and moderate to severe reactions at levels from 2.0 to 2.5 mEq./1. Fine hand tremor, polyuria, and mild thirst may occur during initial therapy and persist. Transient and mild nausea and general discomfort may also appear during initial therapy. These effects usually subside with continued treatment or temporary reduction or cessation of dosage. If persistent, discontinue dosage. Diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination may be early signs of toxicity and may occur at levels below 2.0 mEq./1. At higher levels, ataxia, giddiness, tinnitus, blurred vision, and a large output of dilute urine may be seen. Serum levels above 3.0 mEq./1. may produce a complex clinical picture, involving multiple organs and systems. Serum levels should not exceed 2.0 mEq./1. during acute phase.

The following reactions appear to be related to serum lithium levels, including levels within the therapeutic range: **Neuromuscular**—tremor, muscle hyperirritability (fasciculations, twitching, clonic movements of whole limbs), ataxia, choreo-athetotic movements, hyperactive deep tendon reflex; **Central Nervous System**—blackout spells, epileptiform seizures, slurred speech, dizziness, vertigo, incontinence of urine or feces, somnolence, psychomotor retardation, restlessness, confusion, stupor, coma; **Cardiovascular**—cardiac arrhythmia, hypotension, peripheral circulatory collapse; **Gastrointestinal**—anorexia, nausea, vomiting, diarrhea; **Genitourinary**—albuminuria, oliguria, polyuria, glycosuria; **Dermatologic**—drying and thinning of hair, alopecia, anesthesia of skin, chronic folliculitis, exacerbation of psoriasis, xerosis cutis; **Autonomic**—blurred vision, dry mouth; **Thyroid Abnormalities**—euthyroid goiter and/or hypothyroidism (including myxedema) with lower T_3 and T_4. I^{131} uptake may be elevated; rare cases of hyperthyroidism; **EEG Changes**—diffuse slowing, widening of the frequency spectrum, potentiation and disorganization of background rhythm; **EKG Changes**—reversible flattening, isoelectricity or inversion of T-waves; **Miscellaneous**—fatigue, lethargy, transient scotomata, dehydration, weight loss, tendency to sleep.

Reactions unrelated to dosage include: transient EEG and EKG changes, leukocytosis, headache, diffuse nontoxic goiter with or without hypothyroidism, transient hyperglycemia, generalized pruritus with or without rash, cutaneous ulcers, albuminuria, worsening of organic brain syndromes, excessive weight gain, edematous swelling of ankles or wrists, thirst or polyuria, sometimes resembling diabetes insipidus, and metallic taste. A single case of a syndrome resembling Raynaud's has been reported.

HOW SUPPLIED: 300 mg. capsules in bottles of 100.
300 mg. scored tablets in bottles of 100.

CLORAZEPATE DIPOTASSIUM

Tranxene® CT

Ideal for short-term antianxiety therapy

Acts promptly...tapers gently at discontinuation

Tranxene goes to work in minutes

Nordiazepam uptake is rapid, with pharmacologic effects reported within 30 minutes.[1] Peak serum levels are attained within 1-2 hours after dosing.

Allows post-therapy adjustment time

When administration stops, nordiazepam serum levels taper at a gentle rate. This built-in taper may give your patients more time to adjust to cessation of therapy.[2]

1. Sedation reported in normal volunteers 30 minutes after dosing. Tranxene Drug Monograph 97-0185, p. 9, 1979.
2. The elimination kinetics of an agent can be closely defined, but these cannot at present be directly related to therapeutic or adverse effects.

0043331

Brief Summary

INDICATIONS — Symptomatic relief of anxiety and tension associated with anxiety disorders, other psychoneurotic disorders, transient situational disturbances, and functional or organic disorders. Symptomatic relief of acute alcohol withdrawal.

Effectiveness in long-term use (over 4 months) not assessed by systematic clinical studies. Physician should periodically reassess usefulness for each patient.

CONTRAINDICATIONS — Known hypersensitivity to the drug. Acute narrow angle glaucoma.

WARNINGS — Not for use in depressive neuroses or psychotic reactions. Caution patients against hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles. Advise against simultaneous use of other CNS depressants, and caution patients that effects of alcohol may be increased. Not recommended for patients under 18. Nervousness, insomnia, irritability, diarrhea, muscle aches, and memory impairment have followed abrupt withdrawal from long-term high dosage. Withdrawal symptoms were reported after abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months. Use caution in patients having psychological potential for drug dependence (dependence has been observed in dogs and rabbits).

Pregnancy and Lactation: Minor tranquilizers should almost always be avoided first trimester. Consider possibility of pregnancy before initiating therapy. Patient should consult physician about discontinuation if she becomes pregnant or plans pregnancy. Do not give to nursing mothers.

PRECAUTIONS — Observe usual precautions in depression accompanying anxiety, or in patients with suicidal tendency, or those with impaired renal or hepatic function. Do periodic blood counts and liver function tests during prolonged therapy. Use small doses and gradual increments in the elderly or debilitated.

ADVERSE REACTIONS — Drowsiness, dizziness, various g.i. complaints, nervousness, blurred vision, dry mouth, headache, mental confusion, insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression, slurred speech, abnormal liver and kidney function, decreased hematocrit, decreased systolic blood pressure.

DOSAGE — ANXIETY—Usual daily dose 30 mg or less (start the elderly or debilitated at 7.5-15 mg). Adjust gradually within 15-60 mg daily range. Capsules and scored tablets: divided doses; or once daily h.s. (start patient at 15 mg). Single Dose Tablets, 22.5 mg (for patients stabilized on 7.5 mg t.i.d.) or 11.25 mg: once daily at any hour. ALCOHOL WITHDRAWAL—In divided doses: 1st day 30 mg initially, then 30-60 mg; 2nd day 45-90 mg; 3rd day 22.5-45 mg; 4th day 15-30 mg. Then taper to 15-7.5 mg daily, and discontinue as soon as stable.

INTERACTIONS — Potentiation may occur with ethyl alcohol, hypnotics, barbiturates, narcotics, phenothiazines, MAO inhibitors, other antidepressants.

OVERDOSAGE — Take general measures as for any CNS depressant.

SUPPLIED — Tranxene (clorazepate dipotassium) 3.75, 7.5, and 15 mg capsules and scored tablets. Tranxene-SD Half Strength 11.25 and Tranxene-SD 22.5 mg single dose tablets.

Acts promptly*...tapers gently at discontinuation

(CLORAZEPATE DIPOTASSIUM)

Tranxene® C IV

4306CB

Unexcelled choice for short-term management of anxiety

3.75, 7.5, and 15 mg capsules, scored tablets; 11.25 and 22.5 mg single dose tablets.

*Sedation reported in normal volunteers 30 minutes after dosing; Tranxene Drug Monograph, 97-0185, p. 9, 1979. See overleaf for brief summary.

'STELAZINE' HELPS FIND A WAY THROUGH

The schizophrenic patient is often withdrawn, aloof and emotionally unresponsive. For such patients, 'Stelazine' provides effective, unsurpassed control of these and other psychotic symptoms.

Also important, 'Stelazine' can help patients participate in your therapeutic programs. 'Stelazine' usually does not cause excessive sedation and offers the convenience of b.i.d. dosage.

In fact, no other antipsychotic agent has demonstrated significantly greater overall effectiveness and significantly fewer adverse effects than 'Stelazine'.

'Stelazine'. A first choice for therapy.

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Generally avoid using in patients hypersensitive (e.g., blood dyscrasias, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Additive effect is possible with other C.N.S. depressants, including alcohol.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions, peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./mL.; and Concentrate (intended for institutional use only) 10 mg./mL.

Order Your Copy of the 1980 Membership Directory Now!

The latest listing of APA members (as of January 31, 1980) has just been published. Unlike previous editions, the 1980 Membership Directory, largely at the urging of President Dr. Donald G. Langsley, contains telephone numbers as well as names, addresses, membership class and membership status. A new format provides easy access to the alphabetical and geographical listings.

Another new addition to this Directory is a section containing the names and addresses of District Branch Executive Secretaries. Also included in this Directory is a list of Officers, the Board of Trustees and the Assembly, as well as past APA meetings, past Officers, Honorary and Distinguished Fellows and a membership table. This publication will provide readers with information about the APA and the most comprehensive listing of the membership since the 1977 Biographical Directory.

April 1980. Approximately 300 pages. Order #151. $13.00.

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, are not being considered for publication elsewhere, and have been approved by each author.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. Authors of accepted papers will be asked to sign the following statement:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. In such cases the following wording should be used:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

In addition, authors must obtain letters of permission from publishers for use of extensive quotations (more than 500 words) and of tables and figures that originally appeared elsewhere.

Patient Anonymity

Ethical as well as legal considerations require careful attention to the protection of a patient's anonymity in case reports and elsewhere. Identifying information such as names, initials, hospital numbers, and dates must be avoided. In addition, authors should disguise identifying information about a patient's characteristics and personal history.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 3–4 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by a cover letter indicating that the paper is intended for publication will not be reviewed until such a statement is received. On a separate sheet include the names and mailing addresses of any authors who are not members of APA; they will be sent a complimentary copy of the issue in which their article appears.

Authors will be notified as soon as possible of the receipt of their paper and the number assigned to it. **This number must be included in all further correspondence.** It is imperative that the corresponding author of submitted papers notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings, although not all papers can be published in the *Journal*. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in **final form,** i.e., are ready for review. Authors must **not** submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; **this number must appear in any further communications about the paper.**

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent **(no more than 15 double-spaced pages, including references, tables, and figures).** Brief Communications—2,500 words **(no more than 10 double-spaced pages, including references, tables, and figures).** Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures are used). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 7,500 words **(no more than 25 double-spaced pages—including tables and figures—and 100 references).** All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures, or references, etc. Single case reports should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and **no figures**) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular of Brief Communication length. (A "prompt publication policy" is automatically in effect for Clinical and Research Reports.) These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality and be of major immediate importance to the field. Authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. Because of space limitations not all letters can be printed. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed **double-spaced** throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review may be sent directly to the Book Review Editor, Nancy C. Andreasen, M.D., University of Iowa College of Medicine, 500 Newton Rd., Iowa City, Iowa 52240. Book reviews are usually solicited by the Book Review Editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Book Review Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer.

TYPING AND ARRANGING THE PAPER

All parts of the manuscript, including case reports, quotations, references, and tables, must be **double-spaced** throughout. All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) **nonerasable** bond paper. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Degrees (other than honorary or undergraduate degrees) should be included after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. Provide the department, institution, city, and state where the work was done. If multiple locations and authors were involved, indicate in parentheses which authors were affiliated with each institution. Provide a full address for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications. (No précis is used in the Clinical and Research Reports section.) The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are

both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material: a complete review of the literature is rarely desirable. **Accuracy of citation is the author's responsibility.** References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do **not** arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below, **double-spaced throughout** (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349-365, 1967
3. Jones AB: Long-term administration of tricyclic antidepressants: three-year follow-up. Am J Psychiatry (in press)
4. Smythe JCW (ed): Psychiatry and Human Values. Springfield, Ill, Charles C Thomas, 1971
5. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be **double-spaced** and no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise but descriptive title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3 1/4 inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information availabile in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit classroom or library reserve use by instructors and educational institutions, or of authors who wish to reprint their own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article.

THE AMERICAN PSYCHIATRIC ASSOCIATION
1700 Eighteenth Street, N.W., Washington, D.C. 20009

OFFICERS 1980–1981

President: DONALD G. LANGSLEY
President-Elect: DANIEL X. FREEDMAN
Vice-President: PETER A. MARTIN
Vice-President: ROBERT J. CAMPBELL
Secretary: H. KEITH H. BRODIE
Treasurer: GEORGE H. POLLOCK

ASSEMBLY

Speaker: MELVIN M. LIPSETT
Speaker-Elect: LAWRENCE HARTMANN
Recorder: HOWARD GUREVITZ

MEDICAL DIRECTOR'S OFFICE

Medical Director: MELVIN SABSHIN
Deputy Medical Directors: DONALD W. HAMMERSLEY
CAROLYN B. ROBINOWITZ
JEANNE SPURLOCK
HENRY H. WORK

BOARD OF TRUSTEES

For Three Years: ALAN A. STONE
JOHN J. MCGRATH
PAUL SLAWSON
ELISSA BENEDEK

For Two Years: JULES H. MASSERMAN
RITA R. ROGERS
LEE B. MACHT
WILLIAM B. SPIEGEL

  By Leona L. Bachrach

CHARLES C THOMAS • PUBLISHER

New! MENTAL HEALTH FOR THE NON-PROFESSIONAL

By **Arlene Wood Wiener,** *New Canaan Public Schools, New Canaan, Connecticut, with the assistance of* **Frank Wiener.** *Foreword by* **Barrie S. Greiff.** In this text, all non-professionals working in the mental health field will find plainly presented information that will help them become knowledgeable, skilled, productive members of the mental health treatment team. Secretaries, receptionists, aides, orderlies and other auxiliary mental health personnel will acquire, with this book, a perspective that will help them to maintain an aware and open-minded attitude toward the needs of mental health patients and to generally facilitate the therapeutic situation.

The text constitutes both a general overview of mental health practice and a specific how-to guide. It will be both a handy, daily reference for in-service non-professionals and an invaluable training text for those preparing to work in the area of human services. Contents: *Who are the Professionals? What are Their Roles?; Settings where the Non-Professional May Work and Situations with which the Non-Professional May Deal: An Overview of Mental Health Facilities; The Non-Professional: Qualities, Skills, and Attitudes; The Non-Professional: More Duties and Functions; The Non-Professional: Implicit and Explicit Roles; Mental Disorders; Public Schools and Mental Health; Psychological Theories and Practice: In Brief; Epilogue.* A glossary that defines some 200 commonly used terms in mental health follows the text.

Although prepared primarily for non-professionals working in the psychiatric or psychologic setting, this book offers concise, reliable information to anyone seeking a general description of the mental health field. *'80, 88 pp., cloth-$8.75, paper-$4.95*

New! **The Parents' Guide to WEIGHT CONTROL FOR CHILDREN Ages 5 to 13 Years** *by* **Barbara Krane Feig,** *Chicago. Forewords by* **Ner Littner** *and* **Howard S. Traisman.** *'80, 200 pp., 24 il., cloth-$11.75, paper-$6.95*

New! **SPIRITUAL WELL-BEING OF THE ELDERLY** *edited by* **James A. Thorson,** *Univ. of Nebraska, Omaha, and* **Thomas C. Cook, Jr.,** *National Interfaith Coalition on Aging, Athens, Georgia. (33 Contributors)* After an initial series of chapters that define spiritual well-being, articles are presented that relate the spiritual well-being of the elderly to God, self, the community, and the environment. The final segment places spiritual well-being into a total perspective and provides an overview of the spiritual dimensions of aging. *'80, 260 pp., 1 table, $22.50*

New! **DELIRIUM: Acute Brain Failure in Man** *by* **Z. J. Lipowski,** *Dartmouth Medical School, Hanover, New Hampshire. '80, 576 pp., 5 tables, $39.75*

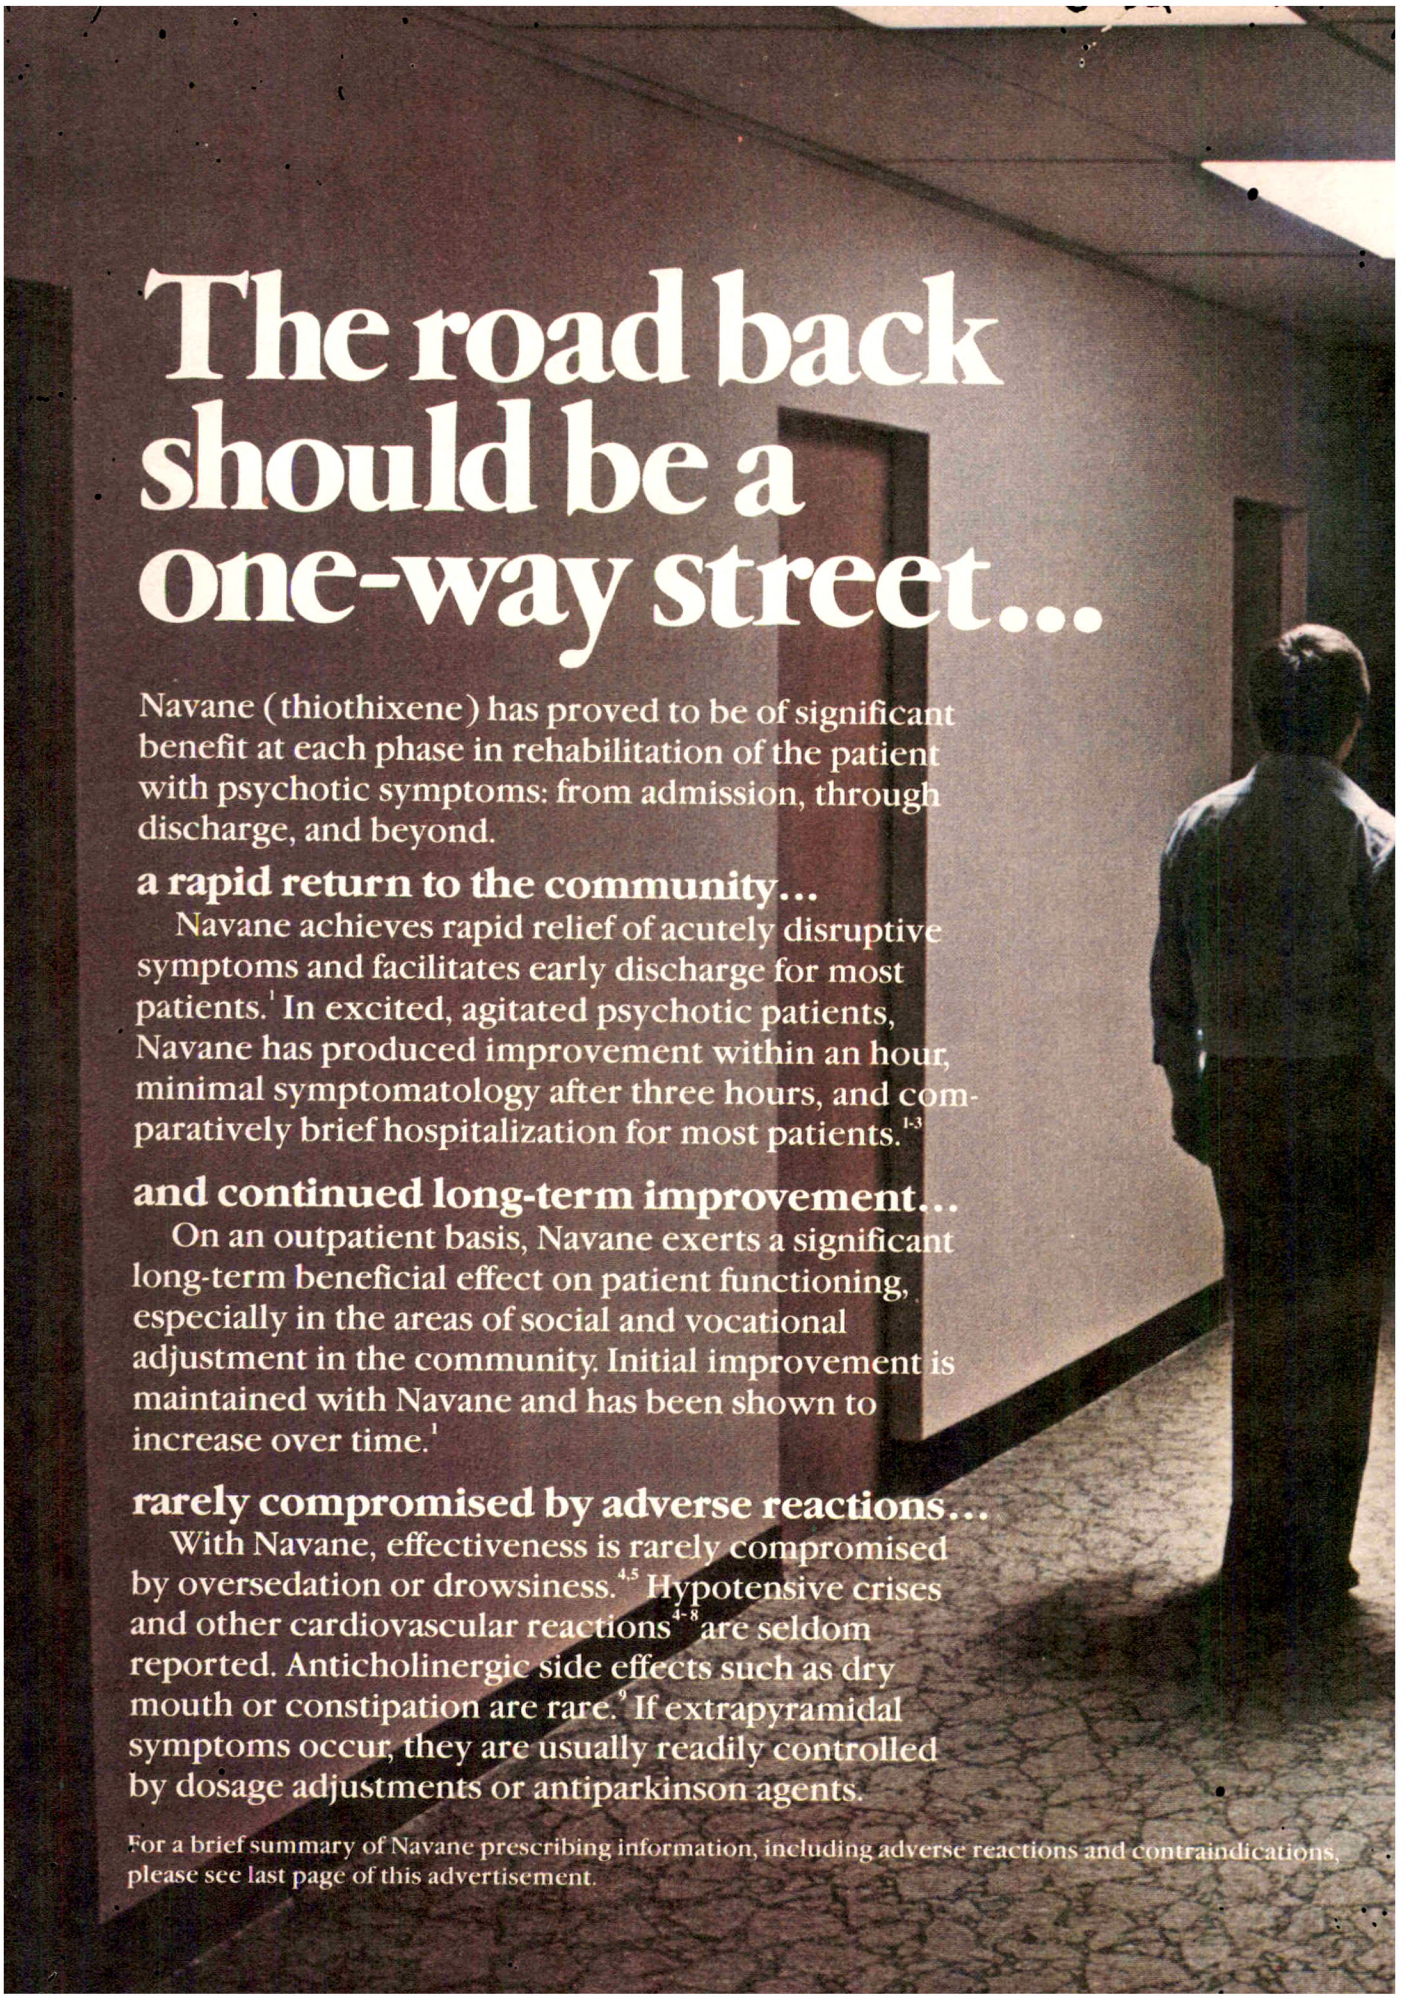
New! **SEX, MOTIVATION, AND THE CRIMINAL OFFENDER** *by* **Robert H. Morneau, Jr.,** *California State Univ., Los Angeles, and* **Robert R. Rockwell,** *Burns International Security Services, Inc., Oakland, California.* This volume synthesizes psychology and law enforcement to help the reader understand the psychosexual component in all crimes as well as in sex crimes *per se. '80, 416 pp., 46 il., $29.75*

THE PARA-PROFESSIONAL IN THE TREATMENT OF ALCOHOLISM: A New Profession (3rd Ptg.) *edited by* **George E. Staub,** *Alcohol Abuse and Alcoholism Program, Los Angeles, and* **Leona M. Kent,** *San Joaquin County Alcoholism Program, Stockton, California. (12 Contributors) '79, 184 pp., 1 table, $11.00*

FAMILY THERAPY AND EVALUATION THROUGH ART *by* **Hanna Yaxa Kwiatkowska.** *Foreword by* **Lyman C. Wynne.** This book describes the special kind of communication provided by the graphic and plastic media and how it can and is being used with families for therapy, evaluation and research. The procedures of family art evaluation are meticulously revealed. *'78, 304 pp., 125 il. (12 in color), 7 tables, $24.00*

New! **WRITING AND DEFENDING A THESIS OR DISSERTATION IN PSYCHOLOGY AND EDUCATION** *by* **Roy Martin,** *Temple Univ., Philadelphia.* Graduate students will find in this text a great deal of practical assistance and information. The author breaks down the thesis/dissertation process into several steps and suggests ways to overcome the hazards of each. Suggestions for working with faculty also are provided. *'80, 120 pp. (4 1/2 x 7), 1 table, $6.75, Lexotone*

New! **URBAN COMMUNITY CARE FOR THE DEVELOPMENTALLY DISABLED** *edited by* **Herbert J. Cohen,** *Albert Einstein College of Medicine, Bronx, New York, and* **David Kligler,** *with the assistance of* **Judith A. Eisler.** *(21 Contributors)* The contributors to this book delineate specific models of care and report on factors affecting program development and service delivery. *'80, 360 pp., 12 il., 13 tables, $25.50*



New! **ANXIETY AND EMOTIONS: Physiological Basis and Treatment** *by* **Desmond Kelly,** *St. George's Hospital, London, England. Foreword by* **W. Horsley Gantt.** This unique monograph explains the way that the mind generates emotions, particularly anxiety, in health and disease. Emphasis is on the brain's limbic system and the important role that it plays in orchestrating biochemical and physiological changes in the human being in response to subjective experiencing. Different treatment modalities for anxiety, including behavior therapy and relaxation techniques, are presented in the final chapter of the book. *'80, 424 pp., 46 il., 40 tables, $24.75*

New! **PARENT EDUCATION AND INTERVENTION HANDBOOK** *edited by* **Richard R. Abidin,** *Univ. of Virginia, Charlottesville. (29 Contributors)* This handbook reviews current developmental psychology regarding parent-child interaction; describes approaches to parent education and intervention for a variety of specific populations; and presents descriptions, ordering information, and reviews of selected parent education and intervention materials. *'80, 608 pp., 1 il., 7 tables, $24.50*

HELP FOR THE DEPRESSED (2nd Ptg.) *by* **Samuel H. Kraines** *and* **Eloise S. Thetford,** *both of Chicago. '79, 272 pp., 9 il., $10.75, paper*

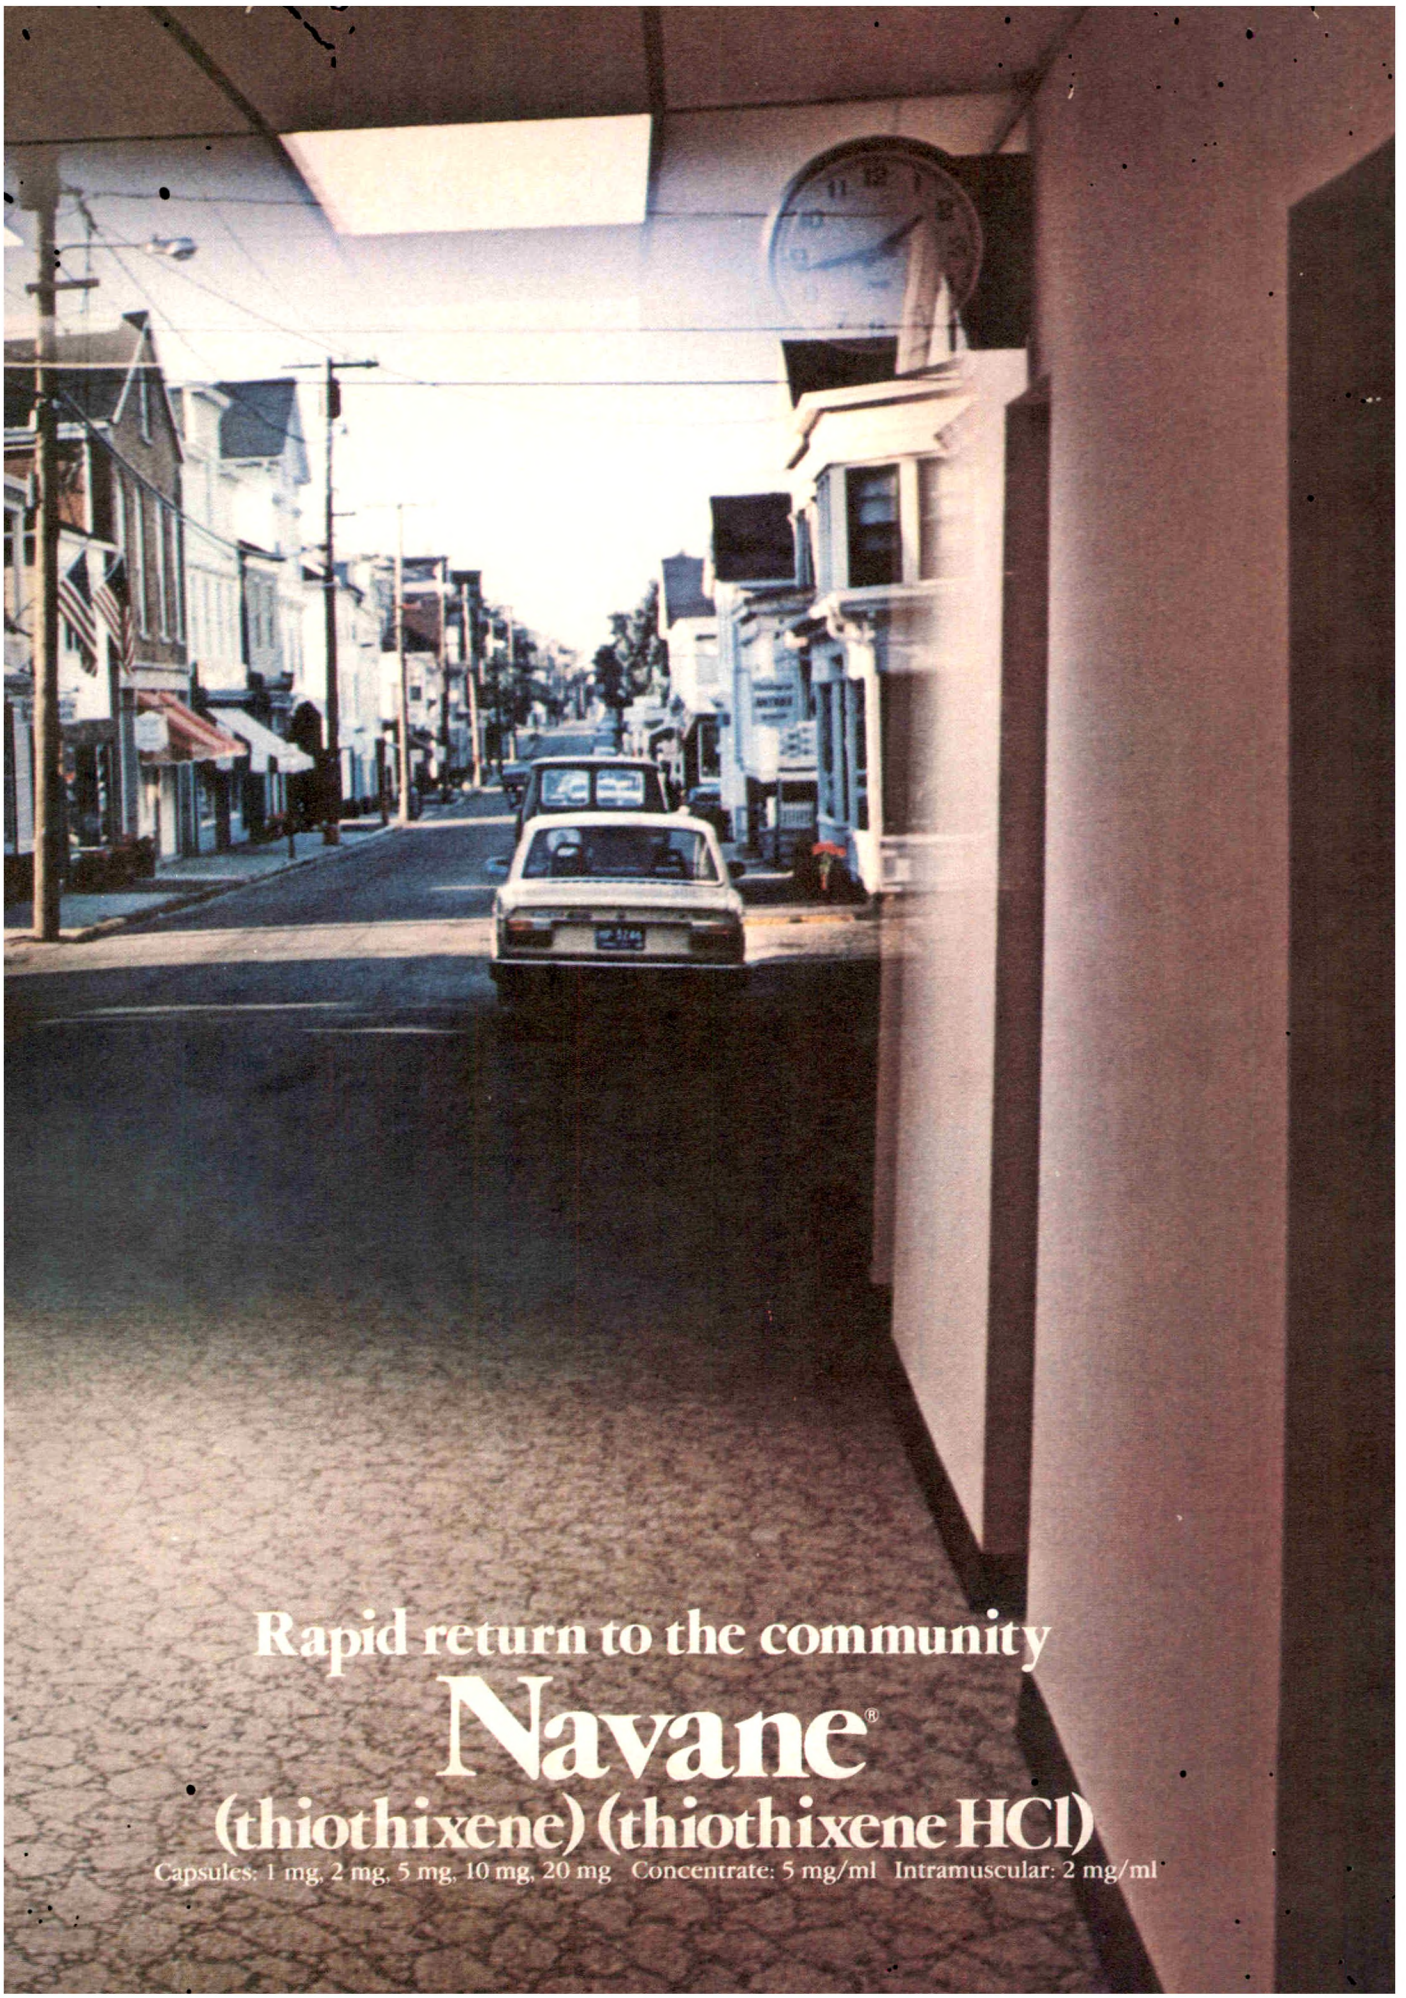
The road back should be a one-way street...

Navane (thiothixene) has proved to be of significant benefit at each phase in rehabilitation of the patient with psychotic symptoms: from admission, through discharge, and beyond.

a rapid return to the community...

Navane achieves rapid relief of acutely disruptive symptoms and facilitates early discharge for most patients.[1] In excited, agitated psychotic patients, Navane has produced improvement within an hour, minimal symptomatology after three hours, and comparatively brief hospitalization for most patients.[1-3]



and continued long-term improvement...

On an outpatient basis, Navane exerts a significant long-term beneficial effect on patient functioning, especially in the areas of social and vocational adjustment in the community. Initial improvement is maintained with Navane and has been shown to increase over time.[1]

rarely compromised by adverse reactions...

With Navane, effectiveness is rarely compromised by oversedation or drowsiness.[4,5] Hypotensive crises and other cardiovascular reactions[4-8] are seldom reported. Anticholinergic side effects such as dry mouth or constipation are rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled by dosage adjustments or antiparkinson agents.

For a brief summary of Navane prescribing information, including adverse reactions and contraindications, please see last page of this advertisement.

Rapid return to the community
Navane®
(thiothixene) (thiothixene HCl)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

Rapid return to the community

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml

Contraindications. Navane (thiothixene) is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*– Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration of Navane to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children– The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration– As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution–For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplan the injectable form as soon as possible. It may be necessary t adjust the dosage when changing from the intramuscular to ora dosage forms. Dosage recommendations for Navane (thiothixene Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate– In milder conditions an initial dose of 2 mg three times daily. If indicated, a subsequen increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily. The usual optimal dose is 20 to 30 mg daily. If indicated, ar increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficia response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Stimulants that may cause convulsions (e.g. picrotoxin or pentylenetetrazol) should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100, 1,000, and unit-dose pack of 100 (10 x 10's). Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100, 500, and unit-dose pack of 100 (10 x 10's).

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10 vials. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.

The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

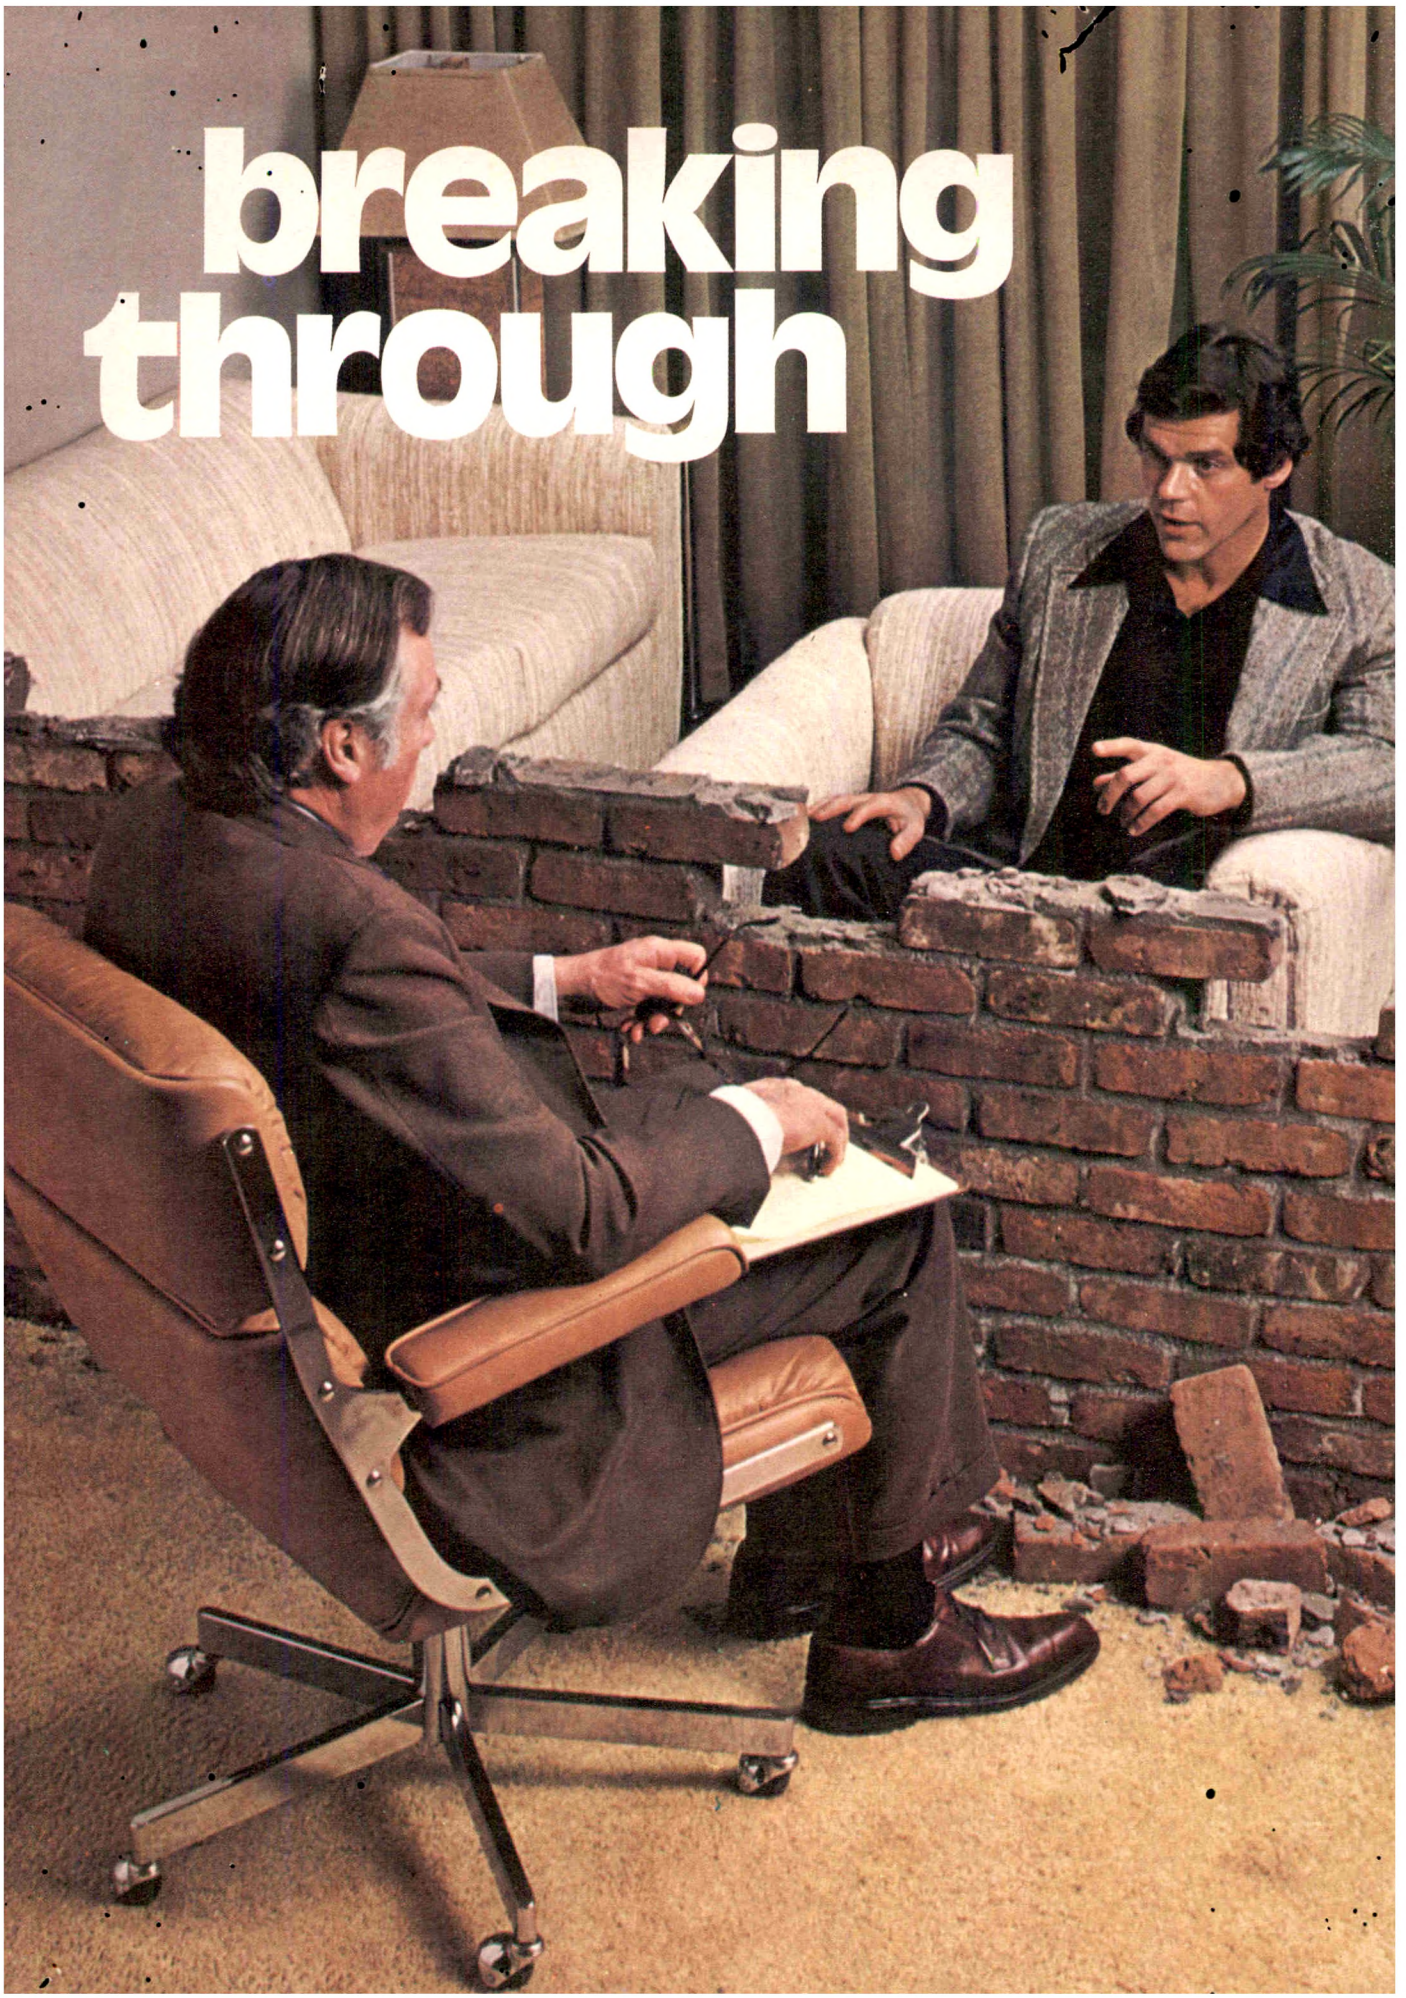
THE BROWN SCHOOLS

An equal opportunity employer. All our programs are accredited by the appropriate Councils of the Joint Commission on Accreditation of Hospitals.

The B24 III...a new generation of electro-convulsive therapy instrumentation from Medcraft.

UL LISTED

Designed with patient and operator safety in mind, this new series of instrumentation meets the rigorous requirements for listing by Underwriters Laboratories — UL 544, Standards for Medical and Dental Equipment. The B24 III provides the physician with the ultimate in precision dosage levels. Consistancy of desired output level is assured with the following features:



- Line Voltage Compensation — allows compensation for fluctuations in incoming line voltages.
- Pre-programmed Voltage Selection — choice of eleven voltage levels from 70 volts to 170 volts.
- Automatic Treatment Timing — adjustable from 0.1 second to 1.0 second with or without Glissando.
- Current Output Indicators — visual assurance of current flow during treatment.

Exclusive Patient Test Module allows a complete systems integrity check of insturmentation prior to treatment. Clinical accuracy and dependability are assured by the use of 100% solid state circuitry. Double shielded transformer provides an additional margin of treatment safety. Write or call for ordering information, specifications and prices.

breaking
through

In marked agitation with depression symptomatic relief may make the patient more accessible and responsive.

Rapid relief of marked agitation in many patients
The tranquilizer component alleviates symptoms of agitation and anxiety within a few days, without apparent dulling of mental acuity. Hypnotic effects from the tranquilizer component appear to be minimal, particularly in patients permitted to remain active. However, TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks.

Highly effective antidepressant action
The antidepressant component relieves symptoms of depression such as poor concentration and feelings of hopelessness as well as early morning awakening; adequate relief of symptoms may take a few weeks or even longer.

Helps break barriers to psychotherapy
As symptoms are relieved, many patients often communicate more effectively, become more cooperative, and are able to return to normal daily activities.

More prescribing convenience
There are now *five* tablet strengths of TRIAVIL for ease of dosage adjustment. For many patients with agitation and depression, you can now initiate therapy with one TRIAVIL® 4-50, containing 4 mg perphenazine and 50 mg amitriptyline HCl, b.i.d. The regimen is simple, economical, and may well enhance patient compliance.

Treatment with TRIAVIL—a balanced view:
TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to overdosage of other drugs or mask other disorders. The possibility of suicide in depressed patients remains until significant remission occurs. Such patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

For marked agitation with depression

dual-action®

TRIAVIL

containing perphenazine and amitriptyline HCl

MSD
MERCK SHARP & DOHME

Copyright © 1979 by Merck & Co., Inc.

Please see following page for a brief summary of prescribing information.

More dosage strengths than any other formulation containing a tranquilizer and an antidepressant

dual-action Triavil®

containing perphenazine and amitriptyline HCl

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-50: Each tablet contains
4 mg perphenazine and 50 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides. There is sufficient experimental evidence to conclude that chronic administration of antipsychotic drugs which increase prolactin secretion has the potential to induce mammary neoplasms in rodents under the appropriate conditions. There are recognized differences in the physiological role of prolactin between rodents and humans. Since there are, at present, no adequate epidemiological studies, the relevance to human mammary cancer risk from prolonged exposure to perphenazine and other antipsychotic drugs is not known.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL, the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

MERCK SHARP & DOHME

The American Psychiatric Association
Introduces

An essential program for clinicians learning to incorporate and utilize DSM-III

THE DSM-III INSTITUTIONAL INSTRUCTION KIT

THE DSM-III INSTITUTIONAL INSTRUCTION KIT acquaints physicians and their staff with:

- the multiaxial evaluation method used to report the official DSM-III diagnosis
- the use of new diagnostic categories in making a differential diagnosis
- the use of criteria as guides in making psychiatric diagnosis for the most significant disorders in:

Affective Disorders
Schizophrenia and Related Psychotic Disorders
Anxiety, Dissociative, and Somatoform Disorders
Personality Disorders
Disorders Usually Arising in Childhood or Adolescence

PROGRAM COMPONENTS:
The Instructor's Kit for workshop leaders contains:

- videotape of nine clinical case simulations
- loose-leaf binder containing:
  - — 4 audiocassettes plus transcripts of original faculty presentations
  - — 39 slides complementing audiotaped presentations
  - — course syllabus, patient histories, worksheets, references
  - — DSM-III diagnosis for each of 30 patient histories

The Participant's Kit for individual workshop members includes:

- course syllabus
- patient histories
- worksheets

CONTINUING MEDICAL EDUCATION (CME) CREDIT:
These learning materials can be used by educational organizations or institutions in the development of, or as an adjunct to, a variety of learning programs for CME Category 1, 2, or 5.

© MONELAB, Inc., 1980

Haldol®
(haloperidol)
tablets/concentrate/injection

Promptly controls psychotic symptoms... usually leaving the patient alert and productive

Highly effective in a wide range of both acute and chronic psychotic disorders,[1-7] such as hallucinations, delusions, suspiciousness, hostility, mania.

Permits aggressive titration to effective dosage levels for optimal response.[1,4]

Facilitates prompt initiation of other therapeutic efforts... and often helps avoid hospitalization.[1-3]

Minimal risk of hypotension, oversedation, or troublesome anticholinergic effects.[2,4-6,8,9] Transient hypotension occurs rarely; severe orthostatic hypotension has not been reported. Although some instances of drowsiness have been reported, marked sedation is rare.

Common side effects easily controlled.[1,2,4-7] Although extrapyramidal symptoms (EPS) have been reported frequently, they are usually dose-related and readily controlled with dose adjustment or antiparkinson drugs. EPS often diminish spontaneously with continued use of HALDOL haloperidol.

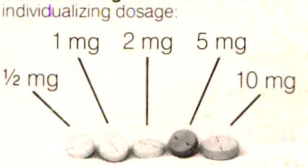
*Not an actual case history, this situation illustrates the action of HALDOL haloperidol as reported in various clinical studies (available on request).

Please turn page for summary of prescribing information.

LIBRARY

concentrate

A tasteless, odorless, colorless liquid concentrate for better patient compliance: 2 mg per ml.



injection

A rapid-acting injection for psychiatric emergencies: 5 mg per ml,* with 1.8 mg methylparaben and 0.2 mg propylparaben per ml, and lactic acid for pH adjustment to 3.4 ± 0.2.

tablets

5 tablet strengths for convenience in individualizing dosage:

HALDOL® (haloperidol)

tablets / concentrate / injection

A dosage form for every therapeutic need

Summary of Prescribing Information

Contraindications: Severe depression, coma, CNS depression due to centrally-acting depressants, Parkinson's disease, hypersensitivity to the drug.

Warnings: ***Usage in Pregnancy:*** Safe use in pregnancy or in women likely to become pregnant has not been established; use only if benefit clearly justifies potential hazards. Infants should not be nursed during drug treatment.

Usage in Children: Safety and effectiveness not established; not recommended in pediatric age group.

Combined Use With Lithium: Patients receiving lithium plus haloperidol should be monitored closely for early evidence of neurological toxicity.

General: Bronchopneumonia, sometimes fatal, has followed use of major tranquilizers, including haloperidol. Prompt remedial therapy should be instituted if dehydration, hemoconcentration or reduced pulmonary ventilation occurs, especially in the elderly. Decreased serum cholesterol and/or cutaneous and ocular changes have been reported with chemically-related drugs, although not with haloperidol. Mental and/or physical abilities required for hazardous tasks or driving may be impaired. Alcohol should be avoided due to possible additive effects and hypotension.

Precautions: Administer cautiously to patients: (1) with severe cardiovascular disorders, due to the possibility of transient hypotension and/or precipitation of anginal pain (if a vasopressor is required, epinephrine should not be used since HALDOL haloperidol may block its vasopressor activity and paradoxical further lowering of blood pressure may occur); (2) receiving anticonvulsant medication since HALDOL haloperidol may lower the convulsive threshold; (3) with known allergies or a history of allergic reactions to drugs; (4) receiving anticoagulants. Concomitant antiparkinson medication, if required, may have to be continued after HALDOL haloperidol is discontinued because of different excretion rates; if both are discontinued simultaneously, extrapyramidal symptoms may occur. Intraocular pressure may increase when anticholinergic drugs, including antiparkinson drugs, are administered concomitantly with HALDOL haloperidol. When HALDOL haloperidol is used for mania in cyclic disorders, there may be a rapid mood swing to depression. Severe neurotoxicity may occur in patients with thyrotoxicosis receiving antipsychotic medication, including HALDOL haloperidol.

Adverse Reactions: ***CNS Effects:*** *Extrapyramidal Reactions:* Neuromuscular (extrapyramidal) reactions have been reported frequently, often during the first few days of treatment. Generally they involved Parkinson-like symptoms which were usually mild to moderately severe and usually reversible. Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently, but were often more severe. Severe extrapyramidal reactions have been reported at relatively low doses. Generally, extrapyramidal symptoms are dose-related since they occur at relatively high doses and disappear or become less severe when the dose is reduced. Antiparkinson drugs may be required. Persistent extrapyramidal reactions have been reported and the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Abrupt discontinuation of short-term antipsychotic therapy is generally uneventful. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain cases these are indistinguishable from "Persistent Tardive Dyskinesia" except for duration. It is unknown whether gradual withdrawal will reduce the occurrence of these signs, but until further evidence is available haloperidol should be gradually withdrawn.

Persistent Tardive Dyskinesia: Although rarely reported with HALDOL haloperidol, tardive dyskinesia may appear during or after long-term therapy. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and sometimes appear irreversible; there is no known effective treatment and all antipsychotic agents should be discontinued. The syndrome may be masked by reinstitution of drug, increasing dosage, or switching to a different antipsychotic agent.

Other CNS Effects: Insomnia, restlessness, anxiety, euphoria, agitation, drowsiness, depression, lethargy, headache, confusion, vertigo, grand mal seizures, and exacerbation of psychotic symptoms.

Cardiovascular Effects: Tachycardia and hypotension. ***Hematologic Effects:*** Reports of mild, usually transient leukopenia and leukocytosis, minimal decreases in red blood cell counts, anemia, or a tendency toward lymphomonocytosis; agranulocytosis rarely reported and only in association with other medication. ***Liver Effects:*** Impaired liver function and/or jaundice reported. ***Dermatologic Reactions:*** Maculopapular and acneiform reactions, isolated cases of photosensitivity, loss of hair. ***Endocrine Disorders:*** Lactation, breast engorgement, mastalgia, menstrual irregularities, gynecomastia, impotence, increased libido, hyperglycemia and hypoglycemia. ***Gastrointestinal Effects:*** Anorexia, constipation, diarrhea, hypersalivation, dyspepsia, nausea and vomiting. ***Autonomic Reactions:*** Dry mouth, blurred vision, urinary retention and diaphoresis. ***Respiratory Effects:*** Laryngospasm, bronchospasm and increased depth of respiration.

The injectable form is intended only for acutely agitated psychotic patients with moderately severe to very severe symptoms.

Caution: Federal law prohibits dispensing without prescription.

Full directions for use should be read before HALDOL haloperidol is administered or prescribed.

HALDOL tablets are manufactured by McNeil Laboratories Co., Dorado, Puerto Rico 00646.

PREVENTING MENTAL ILLNESS

Efforts and Attitudes

A new publication of The Joint Information Service of the American Psychiatric Association and the Mental Health Association
Raymond M. Glasscote; *Eleanor Kohn, Allan Beigel, Merrill F. Raber, Nancy Roeske, Bonnie A. Cox, James R. Raybin, Bernard L. Bloom*

There has long been interest in preventing mental illness, but no great emphasis on financing necessary research and pilot programs. Dramatic discoveries of nutritional, toxic, and infective causes of certain psychoses were made long ago and led to their prevention, but prevention of schizophrenia, mania, sociopathy, and biological depression, among other major disorders, requires further knowledge.

In recent years faith has grown that programs supporting those experiencing heavy stress and privation will provide benefits increasing the likelihood that they will remain functional, productive, and well. This volume provides a balanced, fairminded, and realistic explication of present possibilities and reasonable expectations. It explores a variety of viewpoints and describes in significant detail a variety of prevention-motivated programs for a variety of vulnerable people and provides such outcome information as is presently available.

When depressive symptoms come in a cluster of blues...

Adapin® (doxepin HCl) helps patients see life in all its colors

Improvements noted at one week

Depressed patients often present with fatigue, anorexia, anxiety, mood swings, loss of interest, *and most frequently, early awakening and insomnia*. In a summation of 9 clinical studies involving 198 patients, significant clinical improvement was noted after the first week of doxepin treatment.[1] However, optimal antidepressant response may not be evident for two to three weeks.

Normalized sleep patterns

In a study of clinically depressed patients with symptoms of insomnia, treatment with doxepin significantly reduced difficulty falling asleep, difficulty staying asleep and frequency of early morning awakening.[2]

Low potential for cardiotoxicity

The incidence of tachycardia and hypotension, which have been observed during treatment with tricyclic antidepressants, has been reported infrequently with doxepin. In 452 patients given doxepin, the incidence of tachycardia was 2.88%; in 495 patients, the incidence of hypotension was 2.62%.[3]

Now available...New 75 mg capsules for h.s. dosage

Brief Summary of Prescribing Information ADAPIN® (doxepin HCl) Capsules

Indications–Relief of symptoms of anxiety and depression.

Contraindications–Glaucoma, tendency toward urinary retention or hypersensitivity to doxepin.

Warnings–Adapin has not been evaluated for safety in pregnancy. No evidence of harm to the animal fetus has been shown in reproductive studies. There are no data concerning secretion in human milk, nor on effect in nursing infants.

Usage in children under 12 years of age is not recommended. MAO inhibitors should be discontinued at least two weeks prior to the cautious initiation of therapy with this drug, as serious side-effects and death have been reported with the concomitant use of certain drugs and MAO inhibitors.

In patients who may use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage.

Precautions–Drowsiness may occur and patients should be cautioned against driving a motor vehicle or operating hazardous machinery.

Since suicide is an inherent risk in depressed patients they should be closely supervised while receiving treatment.

Although Adapin has shown effective tranquilizing activity, the possibility of activating or unmasking latent psychotic symptoms should be kept in mind.

This product contains FD&C Yellow No. 5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. Although the overall incidence of FD&C Yellow No. 5 (tartrazine) sensitivity in the general population is low, it is frequently seen in patients who also have aspirin hypersensitivity.

Adverse Reactions–Dry mouth, blurred vision and constipation have been reported. Drowsiness has also been observed.

Adverse effects occurring infrequently include extrapyramidal symptoms, gastrointestinal reactions, secretory effects such as sweating, tachycardia and hypotension. Weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash and pruritus may also occur.

Dosage and Administration–In mild to moderate anxiety and/or depression: 25 mg t.i.d. Increase or decrease the dosage according to individual response. Daily dosage, up to 150 mg may be taken at bedtime without loss of effectiveness. Usual optimum daily dosage is 75 mg to 150 mg per day not to exceed 300 mg per day.

Antianxiety effect usually precedes the antidepressant effect by two or three weeks.

How Supplied–Each capsule contains doxepin, as the hydrochloride. 10 mg, 25 mg, 50 mg, 75 mg and 100 mg capsules in bottles of 100 and 1000.

For complete prescribing information please see package insert or PDR.

ROCHESTER, NEW YORK 14623

Adapin® (doxepin HCl) ... effective single-entity drug with antidepressant and antianxiety effects

A-252

Helps weather
the manic storm

maintenance therapy with Eskalith®

300 mg capsules and
300 mg scored tablets

brand of

lithium carbonate

In manic-depressive patients with a history of mania, 'Eskalith'

- prevents or diminishes the intensity of future episodes
- can increase the intervals between episodes
- helps patients function within normal limits

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

> **WARNING**
> Lithium toxicity is closely related to serum lithium levels, and can occur at doses close to therapeutic levels. Facilities for prompt and accurate serum lithium determinations should be available before initiating therapy.

INDICATIONS: Treatment of manic episodes of manic-depressive illness. Maintenance therapy prevents or diminishes the intensity of subsequent episodes in manic-depressive patients with a history of mania.

WARNINGS: Lithium should generally not be given to patients with significant renal or cardiovascular disease, severe debilitation or dehydration, sodium depletion, or to patients receiving diuretics.

Lithium may prolong the effects of neuromuscular blocking agents. Such agents should be given with caution to patients receiving lithium. Lithium therapy has been reported in some cases to be associated with morphologic changes in the kidneys. The relationship between such changes and renal function has not been established.

Caution patient and family to watch for diarrhea, vomiting, tremor, mild ataxia, drowsiness, or muscular weakness as signs of lithium toxicity, and to discontinue therapy and contact a physician should they occur. Patients receiving combined therapy with lithium and an antipsychotic should be monitored closely for early evidence of neurologic toxicity and treatment discontinued promptly if such signs appear. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery).

Lithium should not be used in pregnancy, especially during the first trimester, unless potential benefits outweigh possible hazards. Except in rare and unusual circumstances, nursing should not be undertaken while a patient is on lithium therapy, since lithium is excreted in human milk.

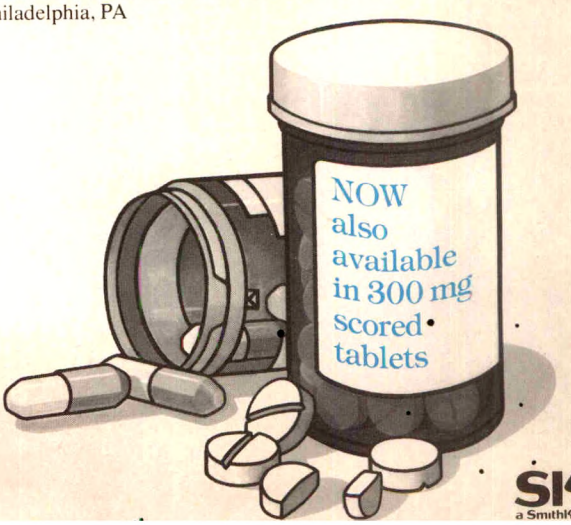
Not recommended for children under 12.

PRECAUTIONS: Lithium tolerance is greater during the acute manic phase and decreases when manic symptoms subside.

Lithium therapy may lead to sodium depletion. Normal diet (including salt) and adequate fluid intake (2500-3000 ml.) must be maintained, at least during initial stabilization period. Protracted sweating or diarrhea can decrease tolerance; in such cases, administer supplemental fluid and salt.

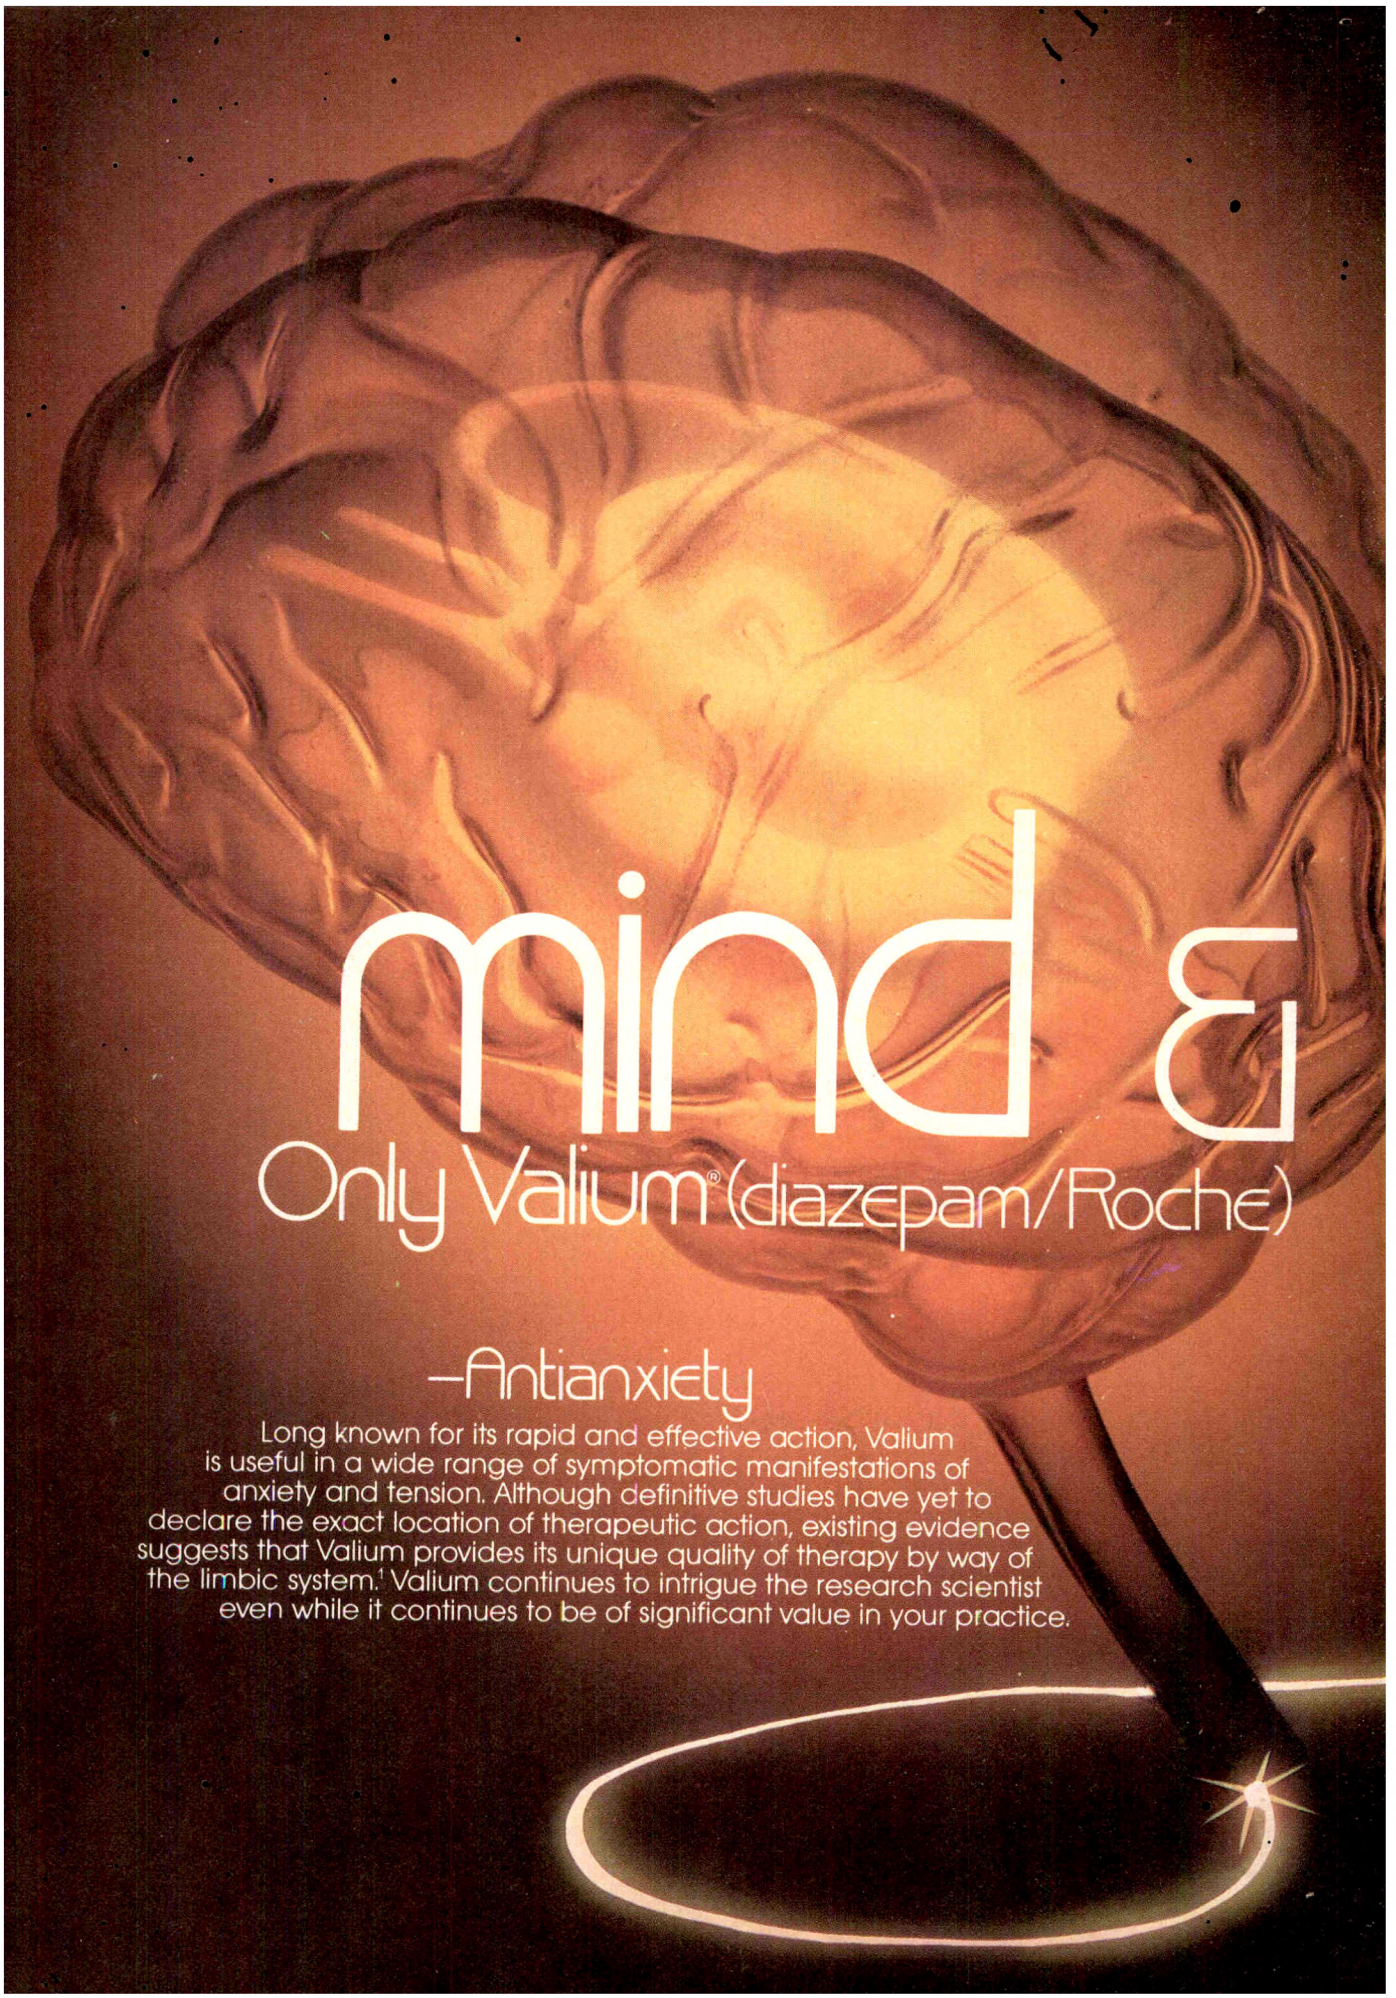
Sweating, diarrhea, and concomitant infection with elevated temperatures may require temporary reduction or cessation of dosage.

Where hypothyroidism exists, thyroid function should be monitored during lithium stabilization and maintenance; where hypothyroidism occurs during stabilization and maintenance, supplemental thyroid treatment may be used.



ADVERSE REACTIONS: Mild to moderate toxic reactions may occur at serum lithium levels from 1.5 to 2.5 mEq./1., and moderate to severe reactions at levels from 2.0 to 2.5 mEq./1. Fine hand tremor, polyuria, and mild thirst may occur during initial therapy and persist. Transient and mild nausea and general discomfort may also appear during initial therapy. These effects usually subside with continued treatment or temporary reduction or cessation of dosage. If persistent, discontinue dosage. Diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination may be early signs of toxicity and may occur at levels below 2.0 mEq./1. At higher levels, ataxia, giddiness, tinnitus, blurred vision, and a large output of dilute urine may be seen. Serum levels above 3.0 mEq./1. may produce a complex clinical picture, involving multiple organs and systems. Serum levels should not exceed 2.0 mEq./1. during acute phase.

The following reactions appear to be related to serum lithium levels, including levels within the therapeutic range: **Neuromuscular**—tremor, muscle hyperirritability (fasciculations, twitching, clonic movements of whole limbs), ataxia, choreo-athetotic movements, hyperactive deep tendon reflex; **Central Nervous System**—blackout spells, epileptiform seizures, slurred speech, dizziness, vertigo, incontinence of urine or feces, somnolence, psychomotor retardation, restlessness, confusion, stupor, coma; **Cardiovascular**—cardiac arrhythmia, hypotension, peripheral circulatory collapse; **Gastrointestinal**—anorexia, nausea, vomiting, diarrhea; **Genitourinary**—albuminuria, oliguria, polyuria, glycosuria; **Dermatologic**—drying and thinning of hair, alopecia, anesthesia of skin, chronic folliculitis, exacerbation of psoriasis, xerosis cutis; **Autonomic**—blurred vision, dry mouth; **Thyroid Abnormalities**—euthyroid goiter and/or hypothyroidism (including myxedema) with lower T_3 and T_4, I^{131} uptake may be elevated; rare cases of hyperthyroidism; **EEG Changes**—diffuse slowing, widening of the frequency spectrum, potentiation and disorganization of background rhythm; **EKG Changes**—reversible flattening, isoelectricity or inversion of T-waves; **Miscellaneous**—fatigue, lethargy, transient scotomata, dehydration, weight loss, tendency to sleep.



Reactions unrelated to dosage include: transient EEG and EKG changes, leukocytosis, headache, diffuse nontoxic goiter with or without hypothyroidism, transient hyperglycemia, generalized pruritus with or without rash, cutaneous ulcers, albuminuria, worsening of organic brain syndromes, excessive weight gain, edematous swelling of ankles or wrists, thirst or polyuria, sometimes resembling diabetes insipidus, and metallic taste. A single case of a syndrome resembling Raynaud's has been reported.

HOW SUPPLIED: 300 mg. capsules in bottles of 100.
300 mg. scored tablets in bottles of 100.

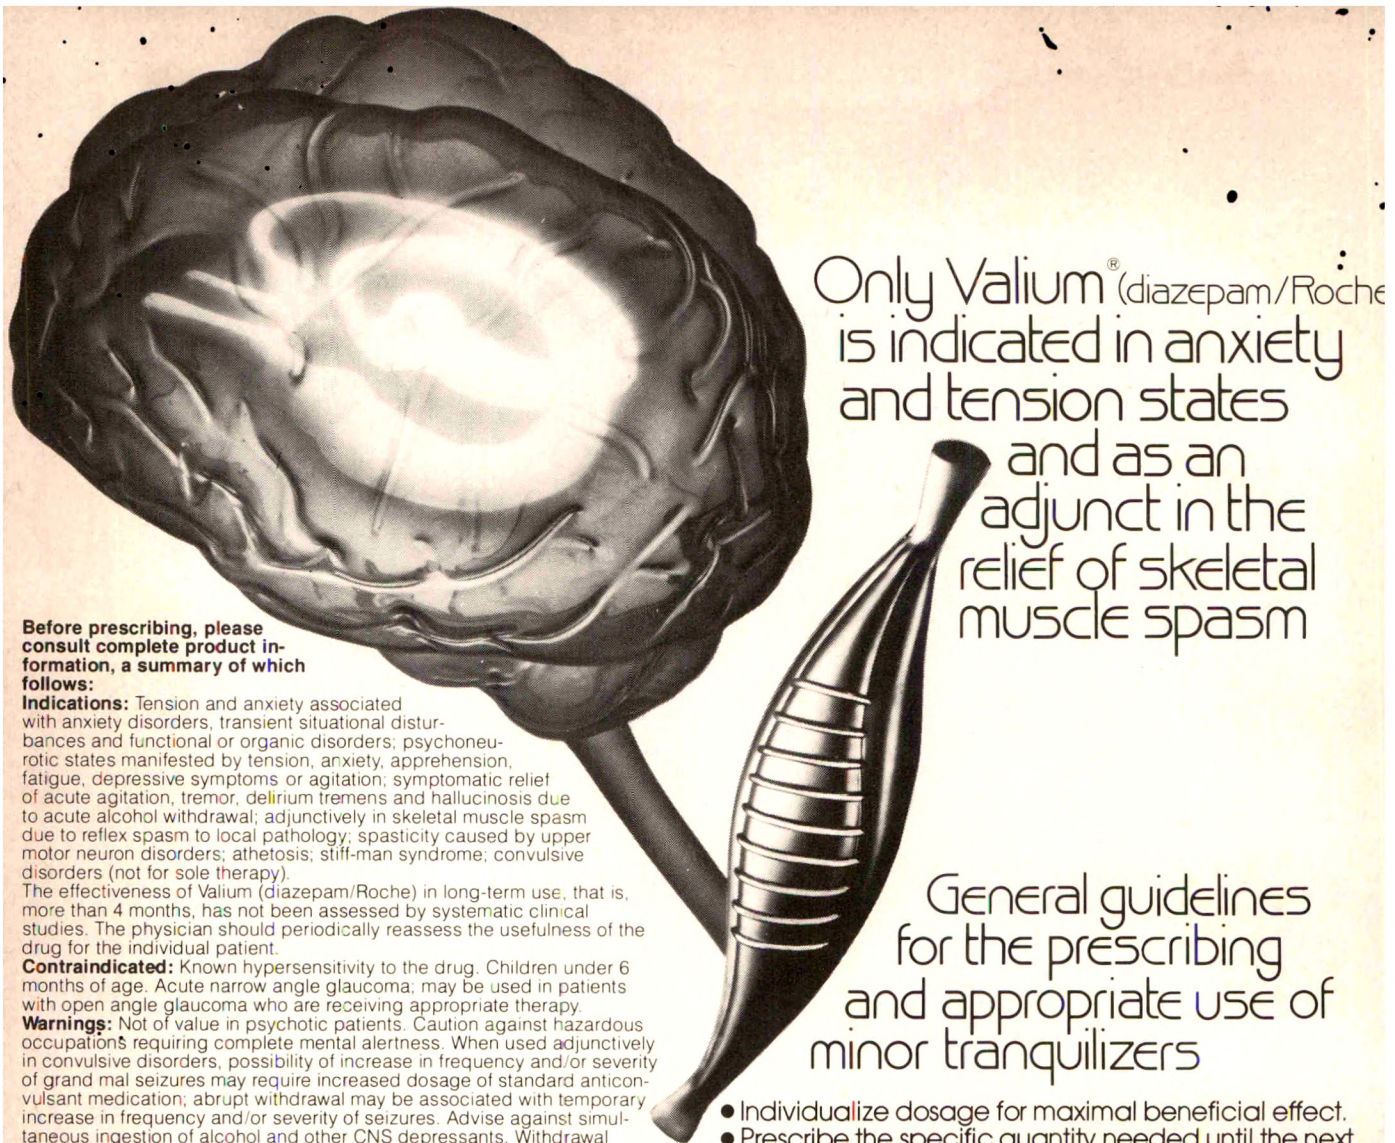
mind &
Only Valium® (diazepam/Roche)
–Antianxiety
Long known for its rapid and effective action, Valium is useful in a wide range of symptomatic manifestations of anxiety and tension. Although definitive studies have yet to declare the exact location of therapeutic action, existing evidence suggests that Valium provides its unique quality of therapy by way of the limbic system.[1] Valium continues to intrigue the research scientist even while it continues to be of significant value in your practice.

–Skeletal muscle relaxant

In addition to producing muscle relaxation by action at the cerebral and spinal levels,[2] Valium may exert direct action on the muscle itself. Experiments have demonstrated that, at a concentration of 10^{-6}M to 10^{-5}M, diazepam directly counteracts contraction in the fast skeletal muscle of the frog.[3] The resulting decrease in muscle contraction is attributed to a net loss of muscle calcium, which is necessary for efficient coupling of action potential to contraction. Further research will be needed to support these preliminary studies and definitely establish the sites of action of Valium in human beings.

muscle has these two distinct effects

2-mg, 5-mg, 10-mg scored tablets



Valium® (IV)

diazepam/Roche

Indicated in anxiety and tension states and as an adjunct in the relief of skeletal muscle spasm.

Please see summary of product information on following page.

ROCHE®

Only Valium® (diazepam/Roche) is indicated in anxiety and tension states and as an adjunct in the relief of skeletal muscle spasm

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety associated with anxiety disorders, transient situational disturbances and functional or organic disorders; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).
The effectiveness of Valium (diazepam/Roche) in long-term use, that is, more than 4 months, has not been assessed by systematic clinical studies. The physician should periodically reassess the usefulness of the drug for the individual patient.

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms similar to those with barbiturates and alcohol have been observed with abrupt discontinuation, usually limited to extended use and excessive doses. Infrequently, milder withdrawal symptoms have been reported following abrupt discontinuation of benzodiazepines after continuous use, generally at higher therapeutic levels, for at least several months. After extended therapy, gradually taper dosage. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

***Usage in Pregnancy:* Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium® Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available in trays of 10.

General guidelines for the prescribing and appropriate use of minor tranquilizers

- Individualize dosage for maximal beneficial effect.
- Prescribe the specific quantity needed until the next checkup period, schedule frequent, periodic reexaminations to monitor results of therapy.
- Establish treatment goals and gradually discontinue medication when these have been met.
- Avoid prescribing for individuals who appear dependency-prone or whose histories indicate the potential for misuse of psychoactive substances, including alcohol.
- Caution patients against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving.
- Advise patients against the ingestion of alcoholic beverages while undergoing therapy with minor tranquilizers.
- Counsel patients to follow label directions, keep medication out of children's reach, and dispose of unused or old medication.
- Caution patients against giving medication to others.
- Avoid abrupt cessation of extended therapy by tapering dosage before discontinuing medication.

ROCHE®
Roche Laboratories
Division of Hoffmann-La Roche Inc.
Nutley, New Jersey 07110

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient.

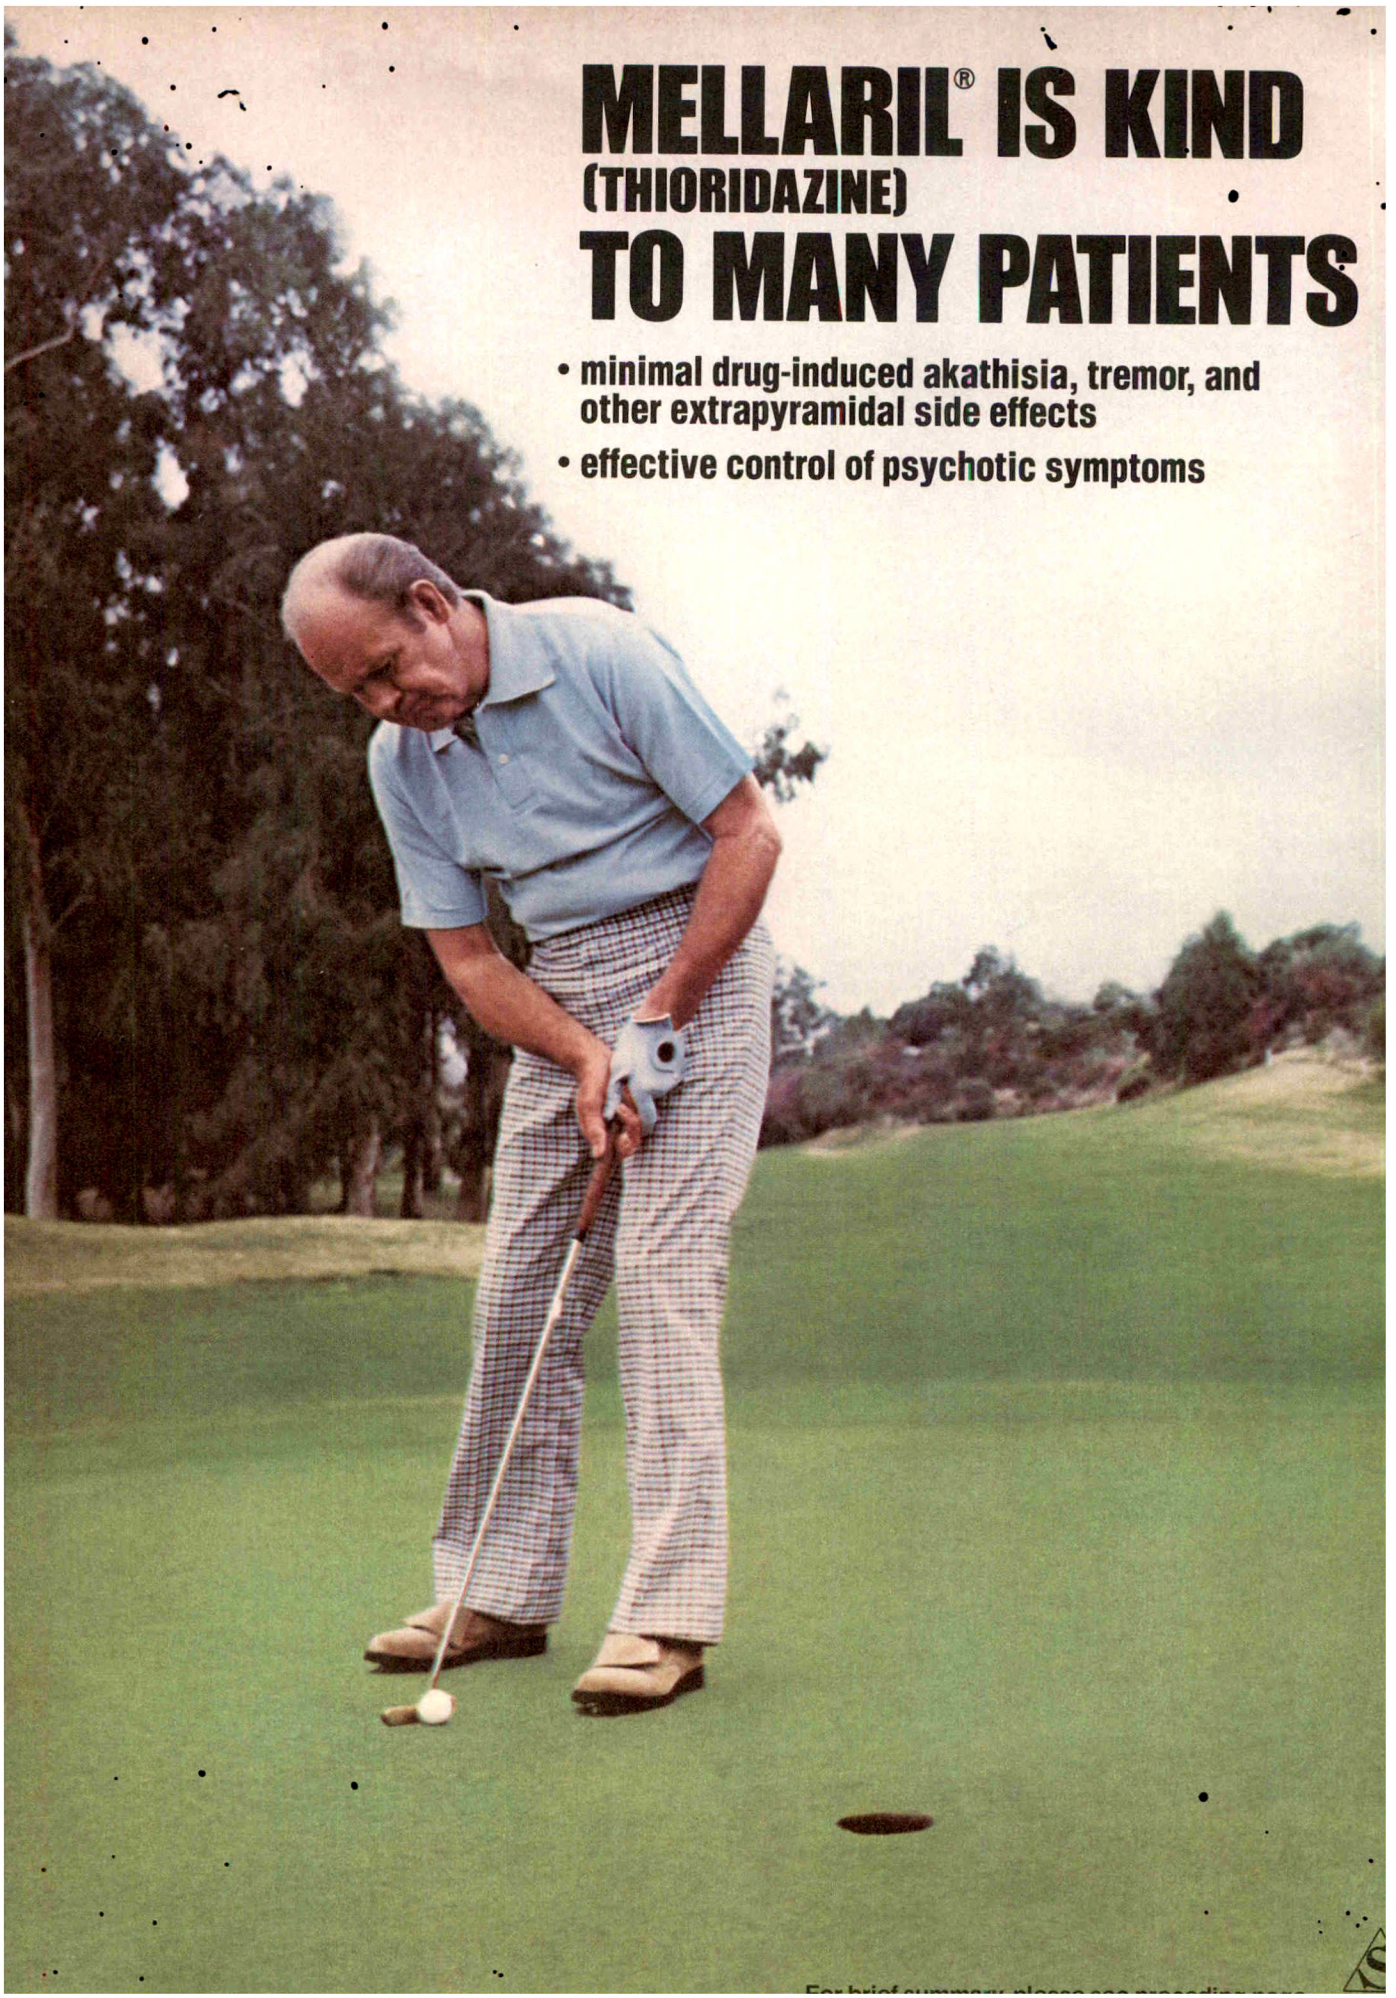
MELLARIL® IS KIND (THIORIDAZINE) TO MANY PATIENTS

- **minimal drug-induced akathisia, tremor, and other extrapyramidal side effects**
- **effective control of psychotic symptoms**



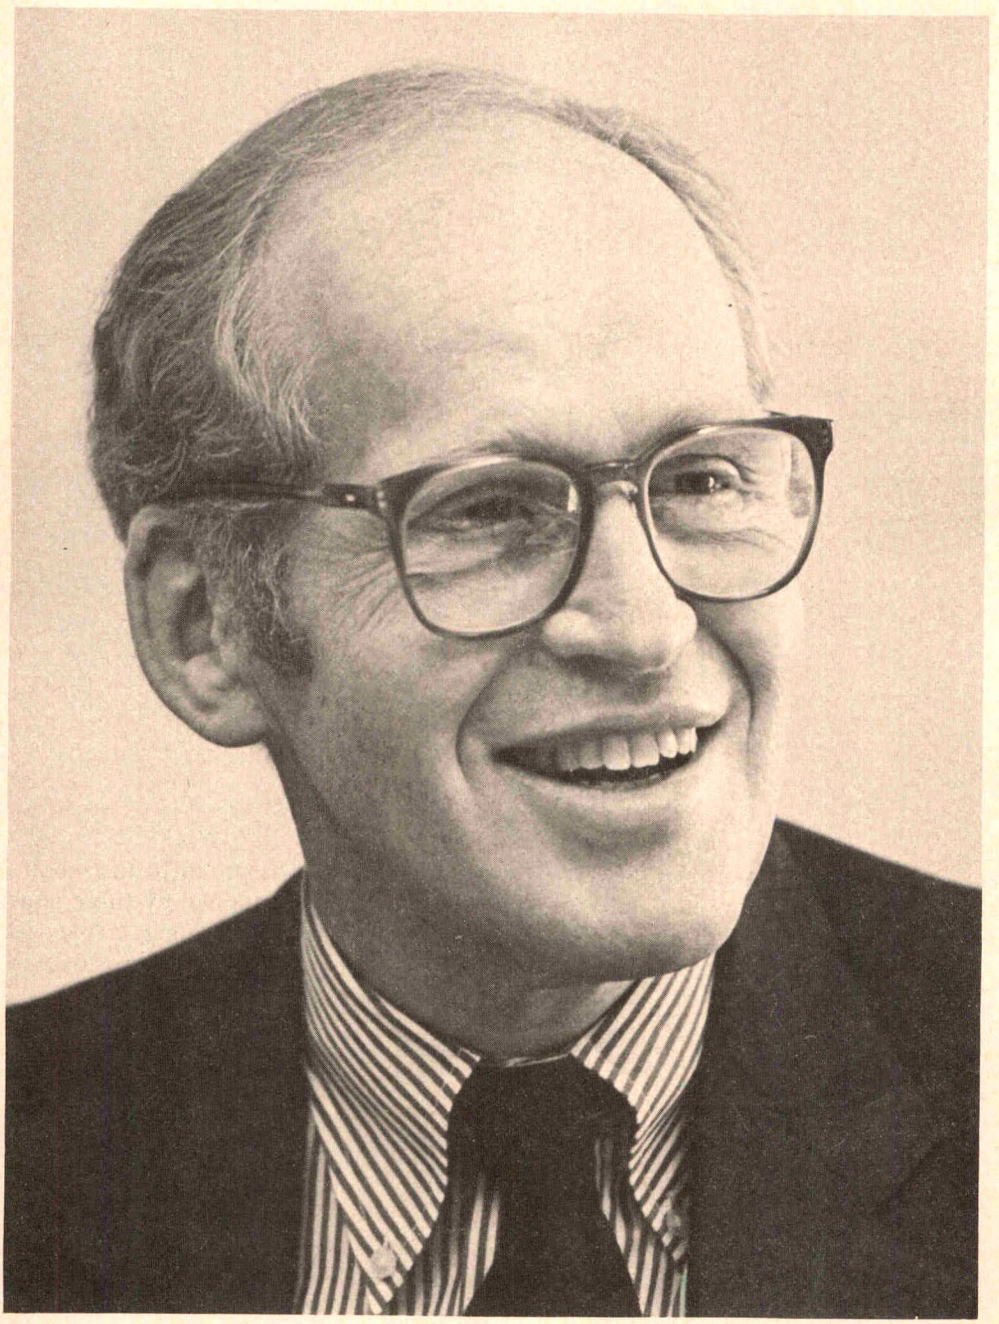
Mellaril® (thioridazine) is kind *two* ways to the patient with psychotic symptoms. It has an impressive record of relieving agitation, excitement, and hallucinations, while successfully helping the patient live and perform in the community. And, unlike other major tranquilizers, Mellaril (thioridazine) causes minimal akathisia or other extrapyramidal symptoms. Mellaril (thioridazine) is contraindicated in patients with hypertensive or hypotensive heart disease of extreme degree.

Effectiveness plus infrequent side effects—that's the kind of kindness the physician likes to see in a major tranquilizer!

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP

MELLARIL-S™ (thioridazine) SUSPENSION, per 5 ml (teaspoon): thioridazine base equivalent to 100 mg thioridazine HCl, USP



MELLARIL® IS KIND
(THIORIDAZINE)
TO MANY PATIENTS
• minimal drug-induced akathisia, tremor, and other extrapyramidal side effects
• effective control of psychotic symptoms

Presidential Address: Conceptual Ambiguity and Morality in Modern Psychiatry

BY ALAN A. STONE, M.D.

Last year in my response to the Presidential Address I rather presumptuously associated myself with the wisdom of the owl of Minerva—the owl that Hegel said only spreads its wings at dusk. From that lofty position I described a new era in psychiatry that I called pragmatic eclecticism, an era in which the four competing models in psychiatry had learned peaceful coexistence. These models—the biological, the psychodynamic, the behavioral, and the social—I suggested were held together by the medical model, which provided clinical coherence if not conceptual clarity. As I present the Presidential Address I must confess that the wings of the owl of Minerva were not fully extended last year. I recant nothing, but I now believe I glided too easily over that qualifying phrase about the absence of conceptual clarity. I intend today therefore to speak about the ambiguity of our eclectic medical model and my concern that having overcome the tyranny of narrow orthodoxy we are now in danger of retreating behind new walls. I shall touch briefly on subjects familiar to you all: racism, homosexuality, and the situation of women. I shall not attempt to deal in a deep way with the substance of these matters; rather, my intention is to examine how American psychiatry has grappled with them. These are all issues which have confronted us in our practice, challenged the moral assumptions that lie concealed in our theories, and confounded us with disputes and acrimony in our Association. It is as we attempt to deal with this kind of issue that the new walls are being built, and it is no accident that each invites psychiatry to take a stand on human values. Human values after all are a crucial link in the chain that binds the self to society. To take a stand on them reveals something about our own selves, our own relation to society, and our own vision of what it means to love and to work.

Many psychiatrists believe that our Association should limit itself to issues that are clearly psychiatric, and they look back at some of the strong positions we have taken on what they consider social issues with regret. Many other psychiatrists believe these social issues are clearly psychiatric; they are proud of what we have done and urge us to do more. I shall claim that what separates these two groups can be understood only as part of the deeper theoretical dilemma in which American psychiatry finds itself, its lack of conceptual clarity. I know I shall be addressing a subject in public that most of us prefer to talk about in private, but my temerity is sustained by three considerations. First, our professional training obliges us to understand conflict rather than repress or deny it, and I believe that in view of recent events the time has come to confront this conflict openly. Second, I have become convinced that the basic limitation of pragmatic eclecticism is that it creates and sustains a mood of caution and expediency in all things, including matters that require moral ambition. Thus, perhaps without thinking it through, we are losing the courage of conscience. Finally, I do not intend to suggest an ultimate solution. I mean only to describe the problem as I encounter it in my own heart and mind.

THE PARABLE OF THE BLACK SERGEANT

I turn to what I have called the parable of the black sergeant. It is a parable about racism, about guilt and forgiveness, and about psychiatric theory and practice. The identifying information in this parable-case

Presented at the 133rd annual meeting of the American Psychiatric Association, San Francisco, Calif., May 3-9, 1980.

Dr. Stone was the 108th President of the American Psychiatric Association. He is Professor of Law and Psychiatry, Faculty of Law and Faculty of Medicine, Harvard University, Cambridge, Mass.

Address reprint requests to Dr. Stone, Langdell Hall, Harvard Law School, Cambridge, Mass. 02138.

history has been disguised for reasons of confidentiality, but the value conflicts it presents are real enough. The patient, a black man, was a supply sergeant. He was caught by the military police stealing a deodorant stick from the post exchange. The Army, which had reason to suspect the sergeant of other thefts and was undeterred by Constitutional restraints on search and seizure, went to his home and reclaimed every piece of Army property that the sergeant could not account for. The pile of supplies—uniforms, blankets, picks and shovels, cartons of canned goods, mess kits, etc.—could have filled a trailer truck. It had all been photographed on the sergeant's front lawn, and that picture became part of his Army medical file.

The Army was determined to court-martial the sergeant, but he had been examined by a civilian psychiatrist who decided that much of what was stolen was of no use to the sergeant and, based on his understanding of the sergeant's psychodynamics, had diagnosed him as a kleptomaniac. This civilian psychiatrist was prepared to testify at court-martial that the stealing was due to unconscious and irresistible impulses. Unhappy with the civilian psychiatrist's report, the Army sent the sergeant to be evaluated at an Army hospital. There he was told repeatedly that anything he said could be used against him at the court-martial. The sergeant took the warning rather impassively, and his Army psychiatrist set to work to construct a very detailed anamnesis over the course of three weeks.

The sergeant, who was a very intelligent man, got caught up in telling the story of his life. He had grown up in a Southern city during the days of racial segregation. A good and serious student from a deeply religious family, he had done well in school and had gone to a small college where he studied literature. After graduation, despite his hopes and dreams, he had found no appropriate work and eventually was drafted into the Korean War. After the war, seeing no alternatives, he remained in the Army to serve his 20 years. As the years passed he became increasingly bitter. He was convinced that life had cheated him because he was black and that the Army, in the work and position it gave him, continued to discriminate against him. Out of this sense of being cheated there grew a sense of entitlement, and he came to feel that he was justified in taking whatever he could whenever he could. He had no sense of being impulsively driven to steal Army property; instead, he stole with a sense of entitlement and reparation in protest of the racist world that had deprived him of his hopes.

It is not clear why this black supply sergeant, despite being warned, told all this to the Army psychiatrist. At any rate he did, and the Army psychiatrist, after puzzling over the diagnostic possibilities (which included paranoid personality and depression), concluded that the sergeant did not have kleptomania or any other mental disorder that should excuse him from responsibility. Subsequently the Army psychiatrist testified at the court-martial. He told the story I have told you while trying to avoid the sergeant's eyes. The sergeant sat there in his dress uniform with his medals, his wife, and their small children. He was sentenced to five years at hard labor. As you may have guessed, I was the Army psychiatrist, and I felt something terrible happened that day. Each time my mind takes me back to that occasion I have a sense of dismay that will not be dissipated.

The Influence of Morality and History

It is tempting when one reflects on this parable of the black sergeant to conclude that it demonstrates no more than the abyss between the moral concerns of the law and the therapeutic concerns of psychiatry. But none of us, I trust, would claim that if a man like the sergeant came voluntarily seeking treatment his psychiatrist would at no point consider moral issues. And how could one treat such a man with no moral perspective and revealing no opinion about racism? Surely a psychiatrist treating the sergeant in 1980 would approach his problems differently than our predecessors would have done in 1940. Psychiatry does not stand outside history or morality, but how do we decide which history and which morality to accept? Is it all a matter of individual choice? Certainly one cannot find the rules controlling what history or morality to accept clearly delineated in the major theories of our biological, psychodynamic, and behavioral paradigms. Psychiatrists are taught to avoid value judgments in their dealings with patients, but I do not believe I make a radical claim when I assert that history and morality are a presence in the therapist's office. The only question is how do they get there.

Let me turn to a narrower question: What role does our practice and our theory play in the courtroom drama of guilt and forgiveness? The legal system, even the Army's legal system, was hesitant to assess guilt in the face of a diagnosis of kleptomania. That diagnosis and the account of human behavior that goes with it invoke the unconscious and the symbolic meaning of the theft. Those who sit in judgment are not asked to consider the sergeant's race and social identity. His behavior is presented in isolation from its historical and cultural context. His kleptomania is understood in the confines of a personality development that repeats a timeless sequence outside culture and history. The psychiatrist applying this kind of theory comprehends the sergeant's motives as nonutilitarian and not intended to offend the system. Such a man can be forgiven; his quarrel is not with us but with his introjects.

On the other hand, the account I gave takes the man as he experiences his life within a particular culture and history. His stealing is understood as part of his response to his predicament. It is his revenge against an unjust system. Such a man cannot be forgiven by our law, but if his judges are willing to condemn the

racism of their society they can lighten his sentence. And if the psychiatrist is willing to lend his authority to the condemnation of a racist society he might even help the judges to reach that lighter sentence. But the moral and historical perspective that might have led me in that direction was not a presence in my office when I examined the sergeant. If in some sense I betrayed the sergeant, and I believe I did, it was because of the historical and moral perspective I brought to the subject of racism.

Psychodynamic Versus Social Considerations

I have carefully distinguished the psychodynamic and the social account of the sergeant's behavior, not only because that is how the two psychiatrists presented them but also to emphasize the radically different moral implications and consequences of the two accounts. There is an irony here that should be underscored. The theory that excludes history and morality has the power to exculpate without disturbing the status quo. Thus the psychiatrist's choice of theory becomes crucial. I shall return to this question of choice. Many of you must be impatient with what seems an artificial distinction because as eclectics we are all accustomed to invoking both accounts. Indeed, the word "psychosocial" seems to have been invented to make this point. Most of us are prepared to believe that there was probably some truth in both accounts of the sergeant's behavior and to insist that anyone who hopes to understand the sergeant must give weight to both, not to mention biological and behavioral factors that are missing from this 20-year-old parable.

Here we touch on the greatest strength of eclecticism and its greatest weakness. Its strength lies in its openness to consider the complexity of the forces that touch our lives. The eclectic psychiatrist sees biological man, moved by dynamic passions and ideals, shaped by culture and shaping culture. The eclectic has the most comprehensive view of what Sartre called the "critical mirror which alone offers man his image." But still that image is only a reflection; even less than a reflection, it is a composite sketch pieced together from the accounts of different witnesses whose vision depends on different theoretical perspectives. It is not just the problem of getting a biological, a psychodynamic, a behavioral, and a social psychiatrist to agree among themselves. How does the individual eclectic psychiatrist who conscientiously considers all of these factors reach a judgment about their relative significance?

This is our greatest weakness. We do not know what weight to give each perspective's account. We can diligently catalogue the different accounts. We can artfully construct Venn diagrams to suggest the possible relationships of these accounts. We can in rare instances assert with confidence the primacy of a particular account. But most often we are condemned to the ultimate ambiguity that is the inevitable consequence of our eclecticism. This is not a problem to be resolved by mere numbers; we do not have a formula or a way of deciding how much something should count. We psychiatrists often say that behavior is overdetermined, but might it be that this concept of overdetermination conceals our very deepest confusion, our inability to order the different considerations? As clinicians each of us treats the whole person, and each day we try to piece together the composite sketch. But we also have a pressing responsibility to ease human suffering. Compassion draws us inevitably to expedient remedies. As pragmatic eclectics uncertain that we have put the pieces of the picture together correctly, we can never be confident that we can distinguish between the sick patient and the sick society.

Lacking that ability and given that it is easier to apply expedient remedies to sick patients than to sick societies, will we not inevitably be led by our clinical responsibilities to distort the composite sketch of the human condition? At the very least we should understand that we might seem to the outside world to be doing just that.

Sensibility at the Cost of Ambiguity[1]

Here is a second irony to be underscored: it was only when our generation of psychiatrists had the courage to overcome the walls of narrow orthodoxy that we confronted our greatest weakness. Only within the narrow paradigms could we construct if not a causal account at least something close to it. When we ventured outside we purchased sensibility at the cost of ambiguity. This theoretical ambiguity is at the very core of the conflicts that confound us. When we testify in court, when we formulate our diagnostic nosology, when we issue position papers, indeed, whenever we attempt to act, we confront this ambiguity. It is no wonder, then, that many psychiatrists are now eager to go back to their narrow paradigms, where they hope to capture the rigor of conceptual clarity that comforts the scientist and to escape from the complexity of human values that accompany a greater sensibility.

Biologists, psychoanalysts, and behaviorists can at least imagine this alternative, but social psychiatrists have no place to hide, no way to narrow their sensibilities. They have always stood outside the walls, urging their colleagues to broaden their horizons. It might even be possible to describe social psychiatry as the fractious adolescent member of the psychiatric family, disrupting the serenity of the household by arguing about values, morality, and social justice, the way all adolescents do. Shall we now expel them? Even if we could, I think it is too late. The broad sensibility they brought to psychiatry has opened eyes that will not be closed.

What I have described thus far is an honest picture

[1]I wish to acknowledge my colleague Roberto Mangabeira Unger, whose ideas were helpful in the formulation of this section.

of my own perplexity, if not of yours. First, I know that I do not abandon history, morality, and human values when I enter my office, but I do not know how I decide what to take in with me. I believe that most of you are in the same position, and for reasons I shall come to shortly I am deeply suspicious of anyone who makes the contrary claim that history, morality, and human values are all irrelevant to psychiatry. Second, I know that I at least am aware of no rules of ordering the different paradigms and their interactions. When I sat in judgment of the black sergeant, I believed that the hard truth of the matter was to be decided by choosing the particular paradigm which best fit the facts of the case. Having chosen the correct paradigm, I applied the explanatory theory of that paradigm and thus never experienced a lack of conceptual clarity. In a sense the four paradigms provided me a framework of differential diagnosis within which I proceeded rigorously, with the skill and objectivity of a scientist. My recognition that the goal of enlightened eclectics like Adolf Meyer was not to choose but to reconcile came when I began to examine the scientific problem of prediction in psychiatry and the moral consequences of my professional activity. Is it possible that our inability to reconcile our paradigms stands in the way of both our scientific and our moral progress?

Thus far I have drawn a picture in which most of psychiatry might seem to stand to one side on the crucial questions of morality and human values, with only social psychiatry on the other side demanding that we get involved in the real world. But during this century all of science has learned painfully and tragically that science is not remote. Every thinking person knows that the physicist's equations play a crucial role in the destiny of humanity. Psychiatry's role is also crucial, although its influence is much more subtle. One of the most remarkable developments in this century is the speed with which the psychiatrist's theories of human nature move from the arcane jargon of our journals through the mass media and into the consciousness of our culture. Psychiatry has played no small part in the transformation of the mind of modern man. This transformation takes place outside our control; theories are bowdlerized and sensationalized. Our drugs are prescribed and self-prescribed everywhere. Other treatment methods have also been coopted and arrayed in the struggles of interpersonal politics. Young people make love after they make therapy. There is in all the affairs of daily living, public and private, the pervasive if subtle influence of our profession.

The most powerful aspect of psychiatry is its contribution to what it means to be a person. This is not under our control, nor can it be in a free society. But we do bear a certain responsibility, and one of the themes in that responsibility is the hidden values in the theories and therapies that originated with us and contribute to the shaping of contemporary consciousness.

The thrust of this analysis is to claim that even without social psychiatry we are not on the other side. We have been engaged in an enterprise that involves concealed positions on human values, moral postures, and even politics. This claim comes not just from unfriendly critics, it comes from responsible colleagues. This is the indictment that confronts those psychiatrists who assert that their psychiatry has nothing to do with these things; although the indictment can be overdrawn and viciously expressed, the fundamental truth in it cannot be gainsaid. Therefore, given the power of our enterprise, whether we like it or not we are in some measure responsible for the influence of these hidden values. It is also important to remember that many of us have wanted to use psychiatry to influence the public to confront and even to treat the sick society through the media. It is not just a matter of aloof scientists being victimized by the vulgarity of the mass media.

HOMOSEXUALITY

One of the first great battlefields in the attack on psychiatry's hidden values was homosexuality. Psychiatrists had long assumed that as part of their humanistic tradition they had brought their scientific perspective to things that were once considered evil. Homosexuality became sickness rather than sin, and this perspective in this century was accepted not only by the secular masses but even by most religious authorities. However, gay liberation brought a different perspective. Their argument was that our judgments about homosexuality as sickness contained hidden values, a limited vision of human sensuality and intimacy, the old morality under a new guise, and perhaps even our own phobic limitations. A campaign was undertaken to remove the diagnosis of homosexuality from the nomenclature. Our Association, after considerable deliberation and not a little acrimony, accepted that perspective. Our Association went even further—it called for an end to legal discrimination against homosexuality. Here I come to the heart of the matter—the relationship of our lack of conceptual clarity to the actions we take. Recall the analysis I have developed here. Each of the four paradigms in psychiatry inevitably had its own theories about homosexuality.

Biological explanations can be sought in the endocrine system, psychodynamic explanations in childhood experiences and the Oedipus complex. Behaviorists can find answers in the sexual gratification reinforcement schedule. The social psychiatrist has the only paradigm that directly addresses the basic issues raised by gay liberation. Imagine if you will the eclectic psychiatrist who accepts all four paradigms but does not know how to reconcile them. Imagine such a psychiatrist who uses the four paradigms as a kind of differential diagnosis. Might that psychiatrist not conclude that there were four different kinds of homosex-

uality and that only the kind described by social psychiatry had been removed from our diagnostic manual?

This analysis may seem far-fetched and bizarre to you, but let me emphasize the structure of my argument. If we have no overarching theory that organizes the theories of the four basic paradigms, those paradigms cannot be changed from the top down, at least not by the logic of a controlling theory. Thus it is possible to argue that for many psychiatrists no fundamental change in their basic approach had occurred. They could go on as before. Therefore, the struggle for those concerned about gay liberation had to continue at a second level, which has two directions.

First, would psychiatry invest more in the effort to influence the public perception of homosexuality? Second, would each of the paradigms undertake the necessary theoretical reformulations essential to a fundamental change? My analysis in no way is meant to demean the decisions our Association reached. Nor do I minimize the importance of what we did. It was not an empty gesture. But I believe the real significance of our actions once again was moral. We changed the moral element in our composite sketch of homosexuality. I understand it as an act of moral compassion producing a small change in public perception. That small change in the long run can have a powerful effect on the most insular theory.

WOMEN'S ISSUES

Perhaps the most penetrating and convincing attack on the hidden and destructive values in psychiatry has related to the subject of women. Indeed, when one has the occasion to read the standard works in psychiatry written before 1970 it no longer seems appropriate to talk about hidden values. It is no wonder, then, that psychiatrists who are concerned about the quality of the composite sketch of women promulgated by their profession and assimilated into our culture should turn to this Association to rectify it. There was obviously a great deal to be rectified, but they confronted an enormous obstacle. There was no diagnosis of female that could be expunged from the diagnostic manual; thus there could be no obvious battlefield. The struggle had to begin at the second level. How far would our Association go in its efforts to rectify the public's perception of women, and how thoroughgoing would be the necessary changes in the theoretical structure of each of the paradigms?

Here I come to the last piece in the structure of my analysis of how American psychiatry deals with these issues, that is, the effect of our own psychology and our own historical situation. As far as I can see, the case against psychiatry as regards women is far more damaging, requires far more than a minor adjustment of our composite sketch, indeed compels each of us to reexamine not only our theories and therapy but also our own lives and relationships. One might even say that psychiatry has only recently discovered that the maxim to love and to work applies to women.

Is it possible that the issues raised concerning women cut deeper in American psychiatry than even racism and homosexuality? That the questions raised in connection with women touch our personal as well as our professional identity? There can be no new psychology of women that does not require a new psychology of men. That makes necessary a new conception of all our human values and all the paradigms of psychiatry. This challenge comes at a time when our profession is struggling—when we have trimmed our sails and yearn for the safety of calmer waters. It comes at a time when many would like to retreat to their narrow paradigm. It comes at a time when the spirit of pragmatic expedience dominates our profession, narrows our horizons, and saps our moral courage.

Most psychiatrists are not by temperament polemical or adversarial. We do not seek out moral controversy. Most of us spend our lives listening compassionately to people who are suffering, whose lives are disrupted by the uncontrolled demands of passion and by the pains of helplessness. We try to be nonjudgmental while we help them weave together the delicate fabric of personal strength that sustains love and intimacy. And we sustain ourselves by small triumphs and acts of private altruism. Our successes often go unnoticed and our failures loom large. Ours is a vulnerable profession, easy to attack and to belittle, but it is a noble profession because it is both a moral and a scientific enterprise.

When we move from the safety of our office to take action in the real world we usually are motivated by the same moral enterprise that guides us in our office: a mixture of compassion, understanding, art, and science. The world outside our office may seem increasingly treacherous. But that treacherous world is already inside our office, if only in microcosm, and our work can never be carried on in a moral and historical vacuum. If like Hercules we were to succeed in lifting our giant of a science from its earthly connections, if we were to cut away all the links that hold self to society, then psychiatry would become a corpse. We will make mistakes if we go forward, but doing nothing can be the worst mistake. What is required of us is moral ambition. Until our composite sketch becomes a true portrait of humanity we must live with our uncertainty; we will grope, we will struggle, and our compassion may be our only guide and comfort.

Am J Psychiatry 137:8, August 1980

Response to the Presidential Address

BY DONALD G. LANGSLEY, M.D.

President Stone has set the theme of human values for this meeting, citing the criteria for maturity suggested by Freud in "Civilization and Its Discontents" (1). In these times, when all of the health professions are changing rapidly, we would do well to review the values of psychiatrists and to place them in the context of changing values in society and government. Let us start with Aristotle, who repeatedly used medicine as a model for the study of values in his Nichomachean and Eudemian Ethics (2). He did so because medicine deals with both life and education. Aristotle divided virtues (called *arete*) into those of the intellect (called *sophia*) and those of the soul (the psyche). How have we psychiatrists fared since Aristotle?

Our medical values are often traced to the Hippocratic tradition, which focused on the responsibility of each physician for his or her patient. Today we expand those concerns to a broad variety of issues affecting health. We have seen a shift from the Flexner tradition, in which science formed the most important base of medicine, to a variety of concerns about ethical, moral, and social issues. As a profession, we are increasingly concerned with social justice. In our roles both as psychiatrists and as citizens, we have come to realize that social action and health are of one piece. We must make that point convincingly when we consider the effect of the social role of women on their mental health.

The values of psychiatry are partially expressed in its ethical statements, in which our usual codes are rules rather than laws. Some cannot be enforced. The law guards against the grosser violations of human rights, but ethics set an ideal higher than law can guarantee. What is legal is not always ethical. Professional ethics must transcend the law for the larger human good.

Robert Moore (3) has reminded us of the sources of medical codes and values. They derive from prayers and oaths written long before the birth of Christ. The Hippocratic Oath from the fourth century B.C. expressed both a convenant among physicians and a set of principles about patient care. With the Middle Ages came the Prayer of Maimonides and a set of Admonita and Epistulae; the Renaissance contributed the Medicus Politicus; and during the eighteenth century a variety of treatises on the duties and character of physicians further amplified the values of the physician in his professional and personal life. Similar codes were suggested by our Chinese colleagues as far back as the sixth century, when Sun Ssu-miao, the father of Chinese medicine, expressed such values in his book *The Thousand Golden Remedies* and again, in the seventeenth century, when Chen Shih Kung proposed 5 commandments and 10 requirements for physicians. The healing professions in all cultures have developed codes of values as they became invested with privileges by their particular society.

Before we ascribe too much to these external codes, we must remind ourselves of the deeper sources of values and the history of their development in the individual. Freud's concepts of unconscious determinism and of a superego and ego shook the world's assumptions about rationality and free will. Our values are rooted at unconscious as well as conscious levels. They are influenced by the experiences of our earliest years of life and are not readily changed by external codes.

It is not only professional codes that influence values. Government has played an increasing role. Health has become a responsibility of government. Governments make life-or-death decisions—even to the giving of life through health care or the withholding of it. Through a series of decisions more often based on economics than on social values, government is in the business of choosing among lives. Because health has become such an enormously costly affair, we see the increasing conflict of values among patients and physicians and those who pay—the government and insurance companies. This complicates the life and work of the physician, who used to say, "I am only concerned with preserving life." Just as we have been cautioned about the power and influence of the military-industrial complex, so should we be mindful of the power and influence of the health care industry, now the second largest in our total economy.

The mass media have had a significant influence on values related to health. Sad to say, the public knows Trapper John and Hawkeye far better than it knows Sir William Osler. The media have fostered the

notion that there is a medicine for every problem, and they have enhanced the demand for high-technology tertiary care medicine. Television doctors cause dissatisfaction in viewers who do not receive the same degree of personal satisfaction from their own physicians. Yet little of this display is for the benefit of the public—media programs are generated to sell pills and other treatments for profit.

Our ethical values also move in the direction of libertarian ideals, a right to health care and the equally important right to refuse. We are concerned that patients have the right to set their own goals and not simply to accept those of the psychiatrist. Many people do not wish to change from behavior that the profession might choose to define as pathological. Do we, then, have the right to define illness with the purpose of insisting that everyone achieve something we call normality or submit to psychotherapy, drugs, or surgery? We are traditionally concerned with privacy and confidentiality. Patients need these in order to develop the trust that makes psychotherapy possible. But at the same time, we are reminded that the public must be protected. In some jurisdictions we are required to warn potential victims or suffer serious consequences.

RESPECT FOR HUMAN LIFE

As physicians we remind ourselves that respect for human life is the basic moral obligation binding our professional decisions. In those circumstances and in this scientific era when we seem on the verge of creating biologic structure, we are entitled to ask what life is and when it begins and ends. We are concerned about the beginnings of what can be an independent life when we consider abortion, just as we are concerned about the termination of life when we consider brain death. We discuss issues of prolonging life through new technologies and treatments, including transplants, chronic dialysis, and new medications, but we need to ask whether this prolongs life in a happy and productive fashion or simply prolongs the existence of certain cells and tissues. We ourselves ask for demonstrations of the efficacy and safety of our treatments, but it is just as often that government and others who pay demand those assurances.

In a sense, the psychiatrist is more sophisticated about motivation and individual values than his or her fellow physicians are. Although we are primarily concerned about advocacy for the patient, his needs as well as his rights, a respect for his autonomy, and the need to obtain his consent, we recognize that the competence to give consent is not a simple or rational process. We among all professions are aware of the irrational bases for making decisions. We know about unconscious reasons for decisions, and of the influences of transference on feeling, thought, and behavior. Is consent given without persuasion or influence and because of rational knowledge, as the courts require? That proposition assumes a different human being than the psychiatrist knows. The physician himself is a major influence. Indeed, as Michael Balint would remind us, the most frequently used drug is the doctor himself. But our special knowledge of behavior does not make us immune from the interests of patients, courts, and legislators—especially those who are lawyers. In his response to the President a year ago (4), Alan Stone reminded us that we have to learn to live with lawyers—as he himself learned to do. But that obligation does not relieve us of the responsibility to educate those same lawyers concerning what we know about human behavior. Our values as psychiatrists are to avoid restriction for each human being—not only the restriction of hospital walls, but also the restrictions and inhibitions of the illness itself and the stigma that society still attaches to mental disorder and, indeed, to a degree, to all of illness.

Tomorrow's psychiatrists—the theme of our meeting next year—are the promise of the future of our profession and its service to humanity. How shall we help them develop their own values? Exhortation alone will not ensure their virtue. Tomorrow's ideals and values derive from the manner in which we select and teach today's students. The major influences on the behavior of tomorrow's psychiatrists are not the facts we present—those change all too frequently. More significant are their identifications during formative years.

Today's students are different from those of yesterday. They approach our profession with a strong commitment to social goals such as peace, civil rights, the reduction of poverty, and the protection of the environment. They prefer egalitarian attitudes and nonauthoritarian relationships with patients. They declare an interest in holistic medicine, the community, and primary care medicine. They are more concerned about responsibility to their own family and themselves and in participation in civic, cultural, and recreational activities. They are healthy, adaptive, and dedicated women and men—more so than my generation.

All professions must constantly reconsider their values. Some of them change, but the past remains a useful guideline for basic values. There are few as meaningful as those outlined by Sir William Osler (5):

> I have three personal ideals. One to do the day's work well. . . . The second . . . to act the Golden Rule . . . towards my professional brethren and towards the patients committed to my care. And the third has been to cultivate such a measure of equanimity as would enable me to bear success with humility, the affection of my friends without pride and to be ready when the day of sorrow and grief came to meet it with . . . courage (pp. 450–451). . . . And, if a fight is for principle and justice, even when failure seems certain . . . cling to your ideal. (p. 8)

I return to Hippocrates, Maimonides, and the other ancients of our profession. Their ghosts would remind

us that our first and most lasting value as psychiatrists should be a concern for our patients. Many people carry the label of patient—those with mild problems and those with problems that interfere with achieving their potential. But our major concerns must be with those who suffer most intensely. I refer to those with acute psychosis or a major affective disorder and those with chronic mental illness, who were often thrust prematurely into communities unprepared to receive them. Many nonpsychiatrists in the mental health field claim to and do possess expertise in psychotherapy and can be of help to some patients with milder forms of mental illness. However, the seriously ill and the chronic patient must not and cannot be neglected by psychiatrists.

The first responsibility of the psychiatrist is to treat the sick. That is the keystone of our value system.

Alan A. Stone, M.D.
One Hundred and Eighth President, 1979–1980

BY SILVIO J. ONESTI, M.D.

It speaks for the wisdom of the members of the American Psychiatric Association that they nominated and elected Alan A. Stone as their 108th President. Alan brought vigor, knowledge, and judgment to the presidency at a time of forceful challenge to accepted ideals. Patients challenge us, legislatures challenge us, insurers challenge us, colleagues in allied professions challenge us, opinions within psychiatry challenge us, expanding scientific knowledge challenges us—all in ways that threaten our ability to provide professional and humane care to those whom we serve. Alan has recognized the challenge, and with it the opportunity to lead psychiatry in the direction of increasing its availability and effectiveness and its commitment to its patients. As psychiatrist, educator, and advocate, and as President of the American Psychiatric Association, he has been nationally and internationally the right spokesman for psychiatry at the right time.

BACKGROUND AND EARLY YEARS

Alan Abraham Stone was born in Boston, Mass., on August 15, 1929. All four of Alan's grandparents had come to the United States from Lithuania to escape oppression and to find opportunity. Alan traces antecedents of his intellectual and scholarly interests to Rabbi Elijah, the famous Vilna Gaon. Alan's grandfathers—both of them hardworking—established small businesses and provided for their families. Both died when Alan's parents were adolescents. Alan's father, one of seven children, worked while continuing his education through Boston University Law School, which in those days did not require a university degree for enrollment.

Alan's father graduated from law school at age 20 and became a law clerk for a judge in the East Boston Court. Soon married, he and Alan's mother took his mother's two sisters in to live with them. Alan's parents had three sons in rapid succession. Alan, the middle son, was born into a supportive family, Jewish in custom and belief but not in adherence to religious dogma.

Alan's father wanted to become the judge of the East Boston Court. Because of that he remained in East Boston after the Jewish population left. Alan grew up surrounded by Italian and Irish people. In that sense he felt himself an outsider. The few remaining elderly Jews who attended the synagogue on holidays did not provide a model of identification for Alan, who looked elsewhere.

Alan found a resource in books. The judge had given Alan's father his library. Alan read Scott, Hugo, de Maupassant, Balzac. One book that influenced him greatly was *This Believing World* (1) by a rabbi who had become an atheist. The idea that all religions were based on fear of death or fear of nature had a great impact on Alan's thinking. He became a secret atheist or at least an agnostic. A sense that the way of the world could be understood through knowledge of human motivation replaced Alan's earlier system of belief.

Social awareness accompanied Alan's psychological awareness. Alan's father, who was practicing law in Boston and East Boston, shared his offices with a black lawyer. He believed in the strength of people coming together; he began a camp for poor children of all races and religions. He believed that if whites and blacks, Catholics, Protestants, and Jews were exposed to each other as children they could overcome their racism. The camp played a large part in Alan's growing years.

As Alan's father and mother had given a home to his mother's younger sisters, so, during the 1930s, Alan's father and mother provided a home for a stream of Jewish refugees, all speaking foreign languages. Alan's parents gave generously, with his mother feeding and sheltering them and his father helping them to find work and homes. Alan's father became a passionate Zionist.

This background of compassion, generosity, responsibility, and devotion molded Alan's youth. Alan was a good son. He read, studied, and was interested in everything around him. It was easy for his father to see promise in Alan and invest in him hopes for the future. Alan's mother found in Alan a thoughtful confidant who returned affection and nurture with companion-

ship. Alan believes that his mother's love and joy in living have been the most vital ingredients in his own life.

One day, when Alan was eight years old, his father brought home a football. Alan began playing, and within a year became part of a green-jerseyed neighborhood team called the Shamrocks, consisting of an Irish boy who was captain, Alan, and the rest all Italian. Football became a large part of Alan's life and was to remain so well into his college career. From football Alan acquired the nickname "Rocky," related more to his indomitable spirit as a linesman than to his surname.

The Boston Latin School for Boys, a special public school for able students, expanded Alan's world. He was outstanding among the brightest and most industrious students in Boston.

FORMATIVE YEARS

Alan entered Harvard University in 1946 among a large group of returning World War II veterans. He began as an economics major, intending to go to law school, until as a sophomore he took a course titled History of Religions. It was *This Believing World* revisited. It explored the phenomenon of conversion as well as the ideas of Judaism and Christianity and added the perspective of anthropology. He switched his major to psychology. Alan played freshman and varsity football. He broke his jaw in a practice during his senior year; his football career ended.

Alan's interest in psychology led him to considerations about aggression. At the time, the frustration-aggression hypothesis was in its ascendancy; it held to the notion that frustrations caused an increase in the instigation of aggression. Alan, guided by Prof. Henry Murray, who had developed the Thematic Apperception Test, administered that test to football players before and after scrimmages and after the season. He found that playing football provided no catharsis at all at the fantasy level; if anything, it seemed to provoke fantasies of retaliatory aggression. Alan elaborated his findings in his senior thesis (2) and received a thesis grade of summa cum laude.

The faculty asked Alan to stay at Harvard in psychology and social relations. Alan consulted Henry Murray, who advised him to go to medical school. Professor Murray said that medicine had a tradition with a past and a future; physicians belonged to a continuing historical and social institution. Alan decided to try to find his roots in medicine and psychiatry. Alan had read a novel about a man who, given a chance to live his life again, repeated the crucial unfortunate choice (3). Alan adopted the idea that one had to take a chance and do what was not expected in order to escape the inevitability of a patterned way. The suggestion of medical school jolted him, yet it sustained his intellectual interest in human nature. He spent a year completing the premedical requirements and applied to medical school.

Alan decided to go to Yale, partly because everyone expected him to go to Harvard and partly because he was impressed by Lawrence Kubie, whose lectures he attended when visiting for his interviews. He did not regret his decision. At Yale he came under the influence and guidance of Ernst Kris.

Alan started a weekly psychiatric study group of medical students that continued for four years. Ernst Kris met with them and encouraged Alan to participate in the longitudinal study of child development at the Yale Child Study Center. He asked Alan to undertake the bibliographic research—to read and catalogue all that had been done before in the way of longitudinal studies. Alan and a fellow student completed this as their medical school thesis; it was later published as a reference book (4).

Alan pursued his interest in child development by taking an internship in pediatrics. He wanted to observe the personality development he had read about in his bibliographic research. Alan thought that after Freud the most interesting contributions to psychiatry and psychoanalysis had come from people such as Ernst Kris, Anna Freud, Melanie Klein, and Erik Erikson, who had worked with children.

He remained at Yale. The Department of Pediatrics there was unique. Milton Senn, as chairman of the Department of Pediatrics and of the Yale Child Study Center, had united excellence in child development, child psychiatry, and child psychoanalysis with excellence in pediatric medicine. At Yale the pediatric intern did everything in the care of the total patient: bacteriology, electrolyte determinations, fluoroscopy, routine blood and urine analyses, care of newborns, care of nursing mothers, developmental assessments, and longitudinal individual and family care. All of the fragmentation of modern medicine was overcome in that department. It has remained for Alan the highest point of his medical experience; he was saving children's lives in a model setting dedicated to furthering the total health and well-being of children and families.

Alan went on into psychiatry. Ernst Kris recommended him to Grete Bibring for psychoanalysis and psychoanalytic training. Alan chose McLean Hospital for his psychiatric residency. He had developed an interest in psychotic patients while an undergraduate student at Harvard and a medical student at Yale. At McLean he could work with psychotic patients in intensive long-term psychotherapy under the close supervision of psychiatrists such as Alfred Stanton and Paul Howard. He took his final year of psychiatric residency training as a fellow in child psychiatry at the James Jackson Putnam Children's Center with Beata Rank. There, he increased his understanding of human development through treating its deviations in severely disturbed, psychotic preschool children.

Alan spent the subsequent two years in the U.S. Army Medical Corps, stationed in Denver and practicing psychiatry. When he returned to his home in Cambridge, he was invited by Mrs. Rank to join her research project regarding children with atypical development. He received a special NIMH grant to do so. He also studied blind retarded children. He observed and reported stereotypic behavior similar to that found in psychotic children (5). He continued to study psychotic adults (6, 7) and adult patients showing constellations of serious suicidal behavior (8–10). His interest in the psychodynamic understanding of severe psychopathologic symptoms united these endeavors.

The following year Alfred Stanton asked Alan to become Director of Residency Training at McLean Hospital, a position Alan held from 1962 to 1968. He is remembered by his residents as a gifted supervisor and educator who observed their therapeutic work directly or through videotapes, consulted on their evaluations, assisted them with psychodynamic formulations, taught them through classic and current literature in seminars at his home, and advised them in their careers. Alan furthered his development by completing his psychoanalytic training at the Boston Psychoanalytic Institute during this period.

PSYCHIATRY AND LAW

Alan's career in law began by chance. Prof. Alan Dershowitz had come to Harvard Law School from Yale. He wanted to introduce at Harvard a course that had originated at Yale called Psychoanalytic Theory and Legal Assumptions, but he needed a psychoanalyst to teach with him. Through Grete Bibring and Erik Erikson he found Alan Stone. Alan, the son of a lawyer and a person who at one time had considered law as a career, found himself in law.

The course the two Alans taught together was a remarkable success. Alan Dershowitz then asked Alan to join him in teaching the more standard course, Psychiatry and Law. Again the course was a success. A crucial ingredient was the dialogue between these two teachers, each committed to his own discipline but each willing to respect the other's view.

Alan decided he had learned all he could about law as an outsider. He received an NIMH grant to spend a year at Harvard Law School. He gave up his position as Director of Residency Training at McLean Hospital and took courses in criminal law, torts, contracts, constitutional law, and family law. Prof. Frank Sander asked him to help teach two courses, Family Law and Human Relations Problems in Legal Practice. The following year Professors Dershowitz and Sander left their courses to Alan. Two years later, at age 40, Alan became Professor of Law and Psychiatry in the Faculty of Law and the Faculty of Medicine at Harvard.

Alan's professorship has allowed him to pursue the life of a scholar; an important element in that life is detailed, rigorous interchange with colleagues in what he calls his "study groups." This tradition, which he began as a medical student, has continued to this day.

Alan entered the field of law at a time of challenge to the assumption that psychiatry and psychoanalysis were value-free sciences. He viewed the legal attacks on the psychiatric establishment not as a narrow problem of forensic psychiatry but as part of a deeper challenge to the hidden value assumptions in psychiatry that become visible in various legal arrangements. Alan has spent the subsequent 10 years of his career examining the moral implications of psychiatry.

Alan became aware of the need for a reasonable spokesman for psychiatry who understood the law and what was taught in law schools, and who knew what was expected of psychiatry and what a constitutional legal system required. Alan views his book *Mental Health and Law: A System in Transition* (11), published in 1975, as a contribution in this regard and his most important book. He formulated positions on a number of issues, such as the standards and procedures for civil commitment, the juvenile justice system, the determination of competency to stand trial, the right to treatment, and the right to refuse treatment. His positions have become those of the psychiatric establishment in briefs presented to state and federal supreme courts. Alan received the Manfred S. Guttmacher Award of the American Psychiatric Association for this work.

As chairman of the Committee on Law of the Group for the Advancement of Psychiatry, Alan was principal author of two reports: *The Right to Abortion: A Psychiatric View* (12) and *The Misuse of Psychiatry in the Administration of Criminal Justice: Competency to Stand Trial* (13). The report on abortion was important personally to Alan because initially he was opposed, both for moral reasons and because he accepted the view that a woman who has had an abortion unconsciously feels that she has committed murder. In the course of meeting with colleagues, Alan reconsidered his previous views, taken from authority rather than from experience and evidence. Although he did not change his moral position, he became convinced that psychiatry had no valid justification for opposing a woman's choice. The report provided him an opportunity to examine how law and psychiatry related to a major social problem. The report was to have practical importance; the New York State legislature used it in passing a law to include nonmedical as well as medical criteria for abortion. This was the prelude to two Supreme Court decisions.

The report on competency to stand trial addressed the controversial issue of the value of a psychiatric opinion in that assessment. The report took Alan's view that the psychiatrist can describe mental processes, but, when the concepts that go into the definitions

of competency and sanity are social, legal, political, and ultimately moral, psychiatrists have nothing in their science that allows them to decide the ultimate legal questions.

Alan has continued to add his ideas regarding the working relationship between law and psychiatry (14, 15). He is widely recognized as a leading spokesman in American psychiatry on this increasingly important subject.

AMERICAN PSYCHIATRIC ASSOCIATION

Alan's career in the American Psychiatric Association began with a request from the Committee of Concerned Psychiatrists that he be a petition candidate for Trustee. Alan agreed with their idea that the members should have a choice of candidates with new views. His election confirmed this. As Trustee he pressed to have the American Psychiatric Association respond to issues confronting it from government and the courts. At the end of his three-year term he sought the Vice-Presidency, again by petition. Alan served as Vice-President for two years and accomplished a great deal. His influence led to the American Psychiatric Association's organizing a Commission on Judicial Action (16) that could prepare amicus curiae briefs for courts throughout the country. He served as chairman. Alan felt it was important to obtain an excellent lawyer as general counsel for the American Psychiatric Association. He found one[1] who not only was a gifted lawyer but who knew the issues as seen by psychiatrists. Alan regards that lawyer, Joel Klein, as a mainstay of our Association. Alan's protective influence allowed the Commission and lawyer to articulate sensible positions that enabled the American Psychiatric Association to present a broad, adaptive, responsible stance.

Alan was nominated for the Presidency and won the election, stating the need for the leadership of the American Psychiatric Association to address social, political, and governmental issues. While President-Elect he held a Guggenheim Fellowship, which supported travel and time to study these issues. Alan also began writing a column for *Psychiatric News* in order to share his ideas with the members.

A major chapter in Alan's life was his participation in a group representing the American Psychiatric Association that was invited by the government of South Africa to investigate alleged abuses of blacks in their psychiatric facilities.[2] The study (17) was a landmark. It meant that the American Psychiatric Association, even with knowledge of the imperfections of psychiatric care in its own country, was willing to provide a model of objective criticism and to recommend specific improvements in the care of 10,000 blacks in mental hospitals in a foreign country. The study showed that psychiatric care in South Africa had been pervasively influenced by the system of apartheid.

While President-Elect, Alan visited Poland by invitation to discuss a new civil commitment law and a new mental health law for that country. Alan was requested to examine General Pyotr Grigorenko, a Russian dissident who had gained entry into the United States. Alan visited Russia, where he spoke to the leading Russian psychiatrist, Prof. Andrei Snezhnevsky, who, at the 1977 meeting of the World Psychiatric Association in Honolulu, had tried unsuccessfully to defend Russian psychiatry against the resolution that political dissidents in Russia were being misdiagnosed as psychiatrically ill and were being detained in mental hospitals. Professor Snezhnevsky stated that the Russians welcomed an examination of General Grigorenko and were certain that a diagnostic team would find him insane. Alan viewed this as a significant opportunity for American psychiatry to make an objective evaluation of a prominent dissident. The diagnostic team found no evidence of insanity and no need for mental hospitalization. Alan sent the report, as he had the report on South Africa, to the responsible authorities to give them an opportunity to comment prior to its publication.

As President of the American Psychiatric Association, Alan in his inaugural address called upon American psychiatry to hold true to its concern for the patient as a whole human being (18). During his presidency, Alan established the Council on Aging to apply this principle in regard to the psychiatric problems of the most rapidly enlarging segment of our population. He added the Council on Government Policy and Law to enable psychiatrists to develop model regulations and submit them to state and federal legislatures.

Alan inherited administrative problems within the American Psychiatric Association that required attention and action: the effects of inflation, the need for new headquarters, the need to raise funds and raise dues, and the need to travel to district branches to obtain informed support. He has taken appropriate steps with all of them.

As President of the American Psychiatric Association, Alan has been a strong spokesman for psychiatry. He testified in Congress, conferred with representatives and senators, appeared on television shows, talked endlessly to reporters who quoted him frequently in newspapers and journals. He addressed issues in a manner that repeatedly helped our patients and strengthened our profession. In his own words, "When our patients' needs are recognized, our profession's future will be secure."

[1]Joel I. Klein, who has written to confirm Alan's commitment to excellence, his humanitarian concerns, and his contribution to the law as a gifted teacher and thinker (personal communication, March 1980).

[2]The group was composed of Charles Pinderhughes, former Trustee; Jeanne Spurlock, Deputy Medical Director; Jack Weinberg, Past President; and Alan Stone, President-Elect.

FAMILY

Alan is a devoted husband and father; his greatest happiness has come from the love and companionship of his wife and children and from experiences shared with them. When the children were young, the family enjoyed summers at Cape Cod and Martha's Vineyard—boating, swimming, playing tennis, collecting mussels and oysters, and reading. Later, vacations were spent in Europe. More recently, Alan and his wife have traveled on holiday to distant parts of the world such as Brazil, Peru, India, and Iran.

Alan met his wife, then Sue Smart, while he was a senior at Harvard and she a sophomore at Radcliffe majoring in poetry. They married as soon as Sue completed college. Sue continued her interest in poetry for several years and a number of her works have been published. When Alan and Sue returned to Cambridge from the Army they collaborated on a book that combined their abilities and interests: *The Abnormal Personality Through Literature* (19). It was an immediate success. Many departments of English and psychology have used it as a textbook, as have a number of medical schools. Published in 1966, the book has been reprinted every year.

Later, when their children were grown, Sue went to law school. Since graduation in 1975 she has worked on projects of public interest. She has served the mentally retarded, has monitored implementation of regulations regarding consent for treatment of the mentally ill, and has examined conflicts of interest of state employees. She is current collaborating with Alan on a book about psychiatric malpractice.

Their daughter, Karen, is 27, a graduate of the University of California at Berkeley and a graduate student in psychology at Harvard; she will do her clinical work next year at McLean Hospital. Their older son, Douglas, is 25, a graduate of Harvard, a Rhodes Scholar, and at present a Karl Taylor Compton Fellow in Physics at the Massachusetts Institute of Technology. Their younger son, David, 22, is a senior at Harvard majoring in psycholinguistics and plans to go to law school. Alan holds his close relationships with all three of his children as very precious. He feels fortunate that he has them all nearby in Cambridge.

Alan and I have been friends for 25 years. We met as pediatric house officers at Yale. We are now psychiatrists and psychoanalysts at Harvard. I respect and esteem him greatly and admire his dedication to everything he values. He has been psychiatrist and psychoanalyst, educator and advocate, for all that is best in our field. He has been loyal to ideas and ideals, articulate in their expression, effective in their pursuit. He has brought his interest in the relationship of psychiatry and values to the attention of his colleagues through his writing and through his selection of the theme of his presidential meeting of the American Psychiatric Association. The theme "To Love and to Work: Human Values in Psychiatry" applies equally to Alan, a man whose love and work and whose human values have benefited those who suffer psychiatric illness and those who attempt to alleviate that suffering.

Tardive Dyskinesia: Review and Update

BY HAROLD L. KLAWANS, M.D., CHRISTOPHER G. GOETZ, M.D., AND STUART PERLIK, M.D.

Tardive dyskinesia is an extrapyramidal syndrome associated with the chronic administration of major neuroleptic agents. The pathogenesis of the disorder appears to relate to chronic striatal dopaminergic receptor site blockade; the pathophysiology of tardive dyskinesia appears to relate to the resultant denervation hypersensitivity. Agents that deplete the brain of dopamine are the mainstay of therapy for tardive dyskinesia. Cholinergic agents that potentially modulate the balance between dopamine and acetycholine in the striatum offer possible additional therapeutic options. Clearly, resumption of neuroleptic therapy is treatment with the presumed pathogenic agent and is to be avoided whenever possible.

Lingual-facial-buccal dyskinesias are abnormal involuntary, persistent movements of the tongue, lips, and facial muscles (1), initially described as an integral part of the hyperkinesias of Huntington's chorea and other choreatic states. Following the introduction of neuroleptics into the practice of psychiatry in France in 1952, reports began to appear in the late 1950s of an extrapyramidal disorder characterized by persistent dyskinesias, often of a lingual-facial-buccal nature, which were associated with the long-term administration of neuroleptics. The late appearance led Uhrbrand and Faurbye in 1960 to apply the term "tardive dyskinesia" (2). By definition this term implies an iatrogenic disease caused by chronic neuroleptic therapy.

The early description of this syndrome emphasized abnormal motor movements affecting the face, the so-called bucco-lingual masticating syndrome. This consisted of involuntary mouthing, chewing, sucking, and licking movements of the tongue. Later, the syndrome description was broadened to include a variety of abnormal muscular manifestations, including choreoathetoid-type movements of the fingers, hands, arms, and feet and flinging or ballistic-type movements, particularly of the arms, as well as axial hyperkinesias and diaphragmatic movement resulting in grunting and difficult breathing. As the condition was studied more, the mouthing movements were further refined to include puckering, panting, smacking, and tongue movements inside the mouth. The clinical picture closely resembles L-dopa-induced dyskinesias and other choreatic disorders, both in the character of the movement abnormality and in the diversity of the individual symptoms.

EPIDEMIOLOGY

A number of population studies have been conducted to establish the frequency of tardive dyskinesia and the significance of such factors as sex, age, and type of underlying psychiatric disease. The prevalence of tardive dyskinesia has been estimated to range from .5% to 56% of patients treated with prolonged neuroleptic agents (3–6). This wide variance may be partly explained by the patient selection process and the diagnostic methods used to define the disorder. Studies of patients who were chronically institutionalized and older tended to report the highest incidence of tardive dyskinesia, but studies that focused on middle-aged and younger patients reported lower incidences (7–9). Smith and associates (10) used the Abnormal Involuntary Movement Scores (AIMS) to assess the prevalence of tardive dyskinesia and demonstrated that abnormal movement scores tended to be more severe with increasing age in both men and women up to age 70. In patients over 70, the mean AIMS decreased in the male population sampled and continued to increase in women. Hence, the often quoted 2:1 female to male prevalence ratio of the disorder was true only for patients over 70; otherwise no sex difference was found.

Other factors besides age and sex that have been studied in relation to the epidemiology of tardive dyskinesia include length of hospitalization, history of neuroleptic-induced extrapyramidal syndromes, and type of schizophrenia. No established patterns have

emerged to clarify these epidemiological issues, and it appears that these are not significant factors in the development of tardive dyskinesia (11). Jus and associates (11) reported a higher prevalence of tardive dyskinesia in those schizophrenic patients who had an insidious rather than an acute onset of their psychiatric disease. They felt, however, that this may be an epiphenomenon because the insidious clinical presentation is more characteristic for the older patient population as a whole. Furthermore, they concluded that the prevalence of tardive dyskinesia was significantly higher if the mean age was higher at the beginning of medication therapy, again a possible reflection of age alone.

The fact that neuroleptic drugs are associated with the development of tardive dyskinesia might suggest that the greater the total amount of neuroleptic a patient has received, the higher the risk of severity of tardive dyskinesia. Two studies (12, 13) suggested an association between total amount of neuroleptic received and tardive dyskinesia, but a third study using higher neuroleptic doses (14) indicated no relation. Smith and associates (10) reviewed drug history and tardive dyskinesia in more than 100 patients and concluded that the total amount of neuroleptic received over many years is not the main variable related to the development of tardive dyskinesia; instead, a positive correlation was found between the maximal amount of neuroleptic administered in any one year and the tardive dyskinesia score. These results suggest that the temporal schedule and daily amount of neuroleptic administered may be epidemiologically more important than the total amount of medicine a patient receives. No increased prevalence of tardive dyskinesia in patients chronically treated with antiparkinsonian drugs has been definitely established (15–17). In fact, one study (5) reported a lower prevalence of tardive dyskinesia in patients receiving concurrent neuroleptic and antiparkinsonian drugs than in patients receiving neuroleptics alone.

NEUROPATHOLOGY

The observation that tardive dyskinesia frequently remains permanent even after discontinuation of antipsychotic drugs (2, 18–21) has led investigators to search for a permanent structural alteration in the brains of patients with tardive dyskinesia. Neuropathological studies following acute or chronic administration of antipsychotic drugs in laboratory animals have not demonstrated specific or localized neuropathologic changes in the brain beyond those secondarily produced by the diverse systemic effects of these drugs (22, 23). There is a single report of reduced neuronal cell count in the basal ganglia of rats chronically receiving phenothiazines (24), but this is of uncertain importance because gliosis or degenerative changes were not observed. Postmortem neuropathologic changes following chronic phenothiazine treatment in patients without extrapyramidal syndromes have usually consisted of scattered areas of neuronal degeneration and gliosis without convincing localization (22). Individual patients with drug-induced parkinsonism or tardive dyskinesias have been reported to have postmortem changes in the globus pallidus and putamen (25), in the caudate nucleus and substantia nigrae (26), and in the inferior olive, but other investigators (27) have reported no significant neuropathologic abnormality in patients with tardive dyskinesias.

Christensen and associates (28) have reported the presence of neuronal degeneration and gliosis of the substantia nigrae in 27 of 28 brains from patients with chronic oral dyskinesias, 21 cases of which were attributed to antipsychotic drugs. Only 7 of 28 matched control brains showed similar changes. Although the reported nigral degeneration and gliosis may represent a toxic effect of the drug, their occurrence in some elderly individuals who did not have tardive dyskinesia raises the possibility that they may be accompanying events of aging and not directly related to the appearance of tardive dyskinesia. The fact that no obvious anatomical alterations are associated with the development of tardive dyskinesia has led investigators away from microscopic studies and toward a more thorough evaluation of receptor site dynamics, neurochemistry, and pharmacology of the disorder.

PATHOGENESIS AND PATHOPHYSIOLOGY

Although the pathologic sequence of changes underlying the development of tardive dyskinesia remains unknown, the similarity of the abnormal movements to other forms of chorea suggests a common biochemical basis. A number of clinical and pharmacologic observations have helped to clarify the pathophysiology of the movements seen in tardive dyskinesia; these observations have etiologic as well as therapeutic implications. In summary, there is substantial evidence that the pathogenesis of tardive dyskinesia relates to chronic dopamine receptor site blockade; the pathophysiology of the disorder relates to the resultant receptor site hypersensitivity.

The first clues concerning the pathophysiology of tardive dyskinesias came from the observation that the neuroleptics—agents associated with the development of tardive dyskinesias—are the same agents known to cause drug-induced parkinsonism. Parkinsonism is felt to result from deficient dopaminergic activity in the striatum (29). The fact that the neuroleptics can induce a parkinsonian syndrome suggests that these agents may alter central dopaminergic balance and thereby chemically simulate the structural abnormality seen in Parkinson's disease. Biochemical studies have corroborated these hypotheses and have shown that the

neuroleptics act by blocking dopamine receptor sites in the limbic system and the striatum (30). This blockade of dopamine receptors in the striatum is felt to underlie the neuroleptic-induced parkinsonism so often seen within the first weeks or months after neuroleptic induction. These studies show that neuroleptics affect the dopaminergic system and that, at least initially, the effect is one of functional underactivity of dopamine at dopamine receptor sites of the striatum.

This blockade may be thought of as a form of chemical denervation or functional inactivation of dopamine receptors in the striatum. If the blockade is complete at any receptor site, the receptor is prevented from receiving its normal neurotransmitter influence. This does not imply that the blockade is complete for all dopaminergic receptors throughout the striatum. The concept is important because it implies that not all receptors are blocked to the same extent by a single agent. If the latter were true, chemical denervation could occur only following complete blockage of all dopamine receptors, which would necessarily be accompanied by a severe form of drug-induced parkinsonism.

A second clue concerning the pathophysiology of tardive dyskinesias comes from the observation that these dyskinesias are remarkably similar to and often indistinguishable from the abnormal movements seen in Huntington's disease and L-dopa-induced dyskinesias. These latter two movement disorders are felt to relate to a heightened response of the dopamine receptor sites in the striatum. The similarity of tardive dyskinesias to movement disorders whose pathophysiology is better understood suggests that tardive dyskinesias, too, may relate to altered sensitivity of the striatal dopaminergic system.

Whereas parkinsonism results from underactivity of the dopaminergic system, tardive dyskinesias appear to result from overactivity. The neuroleptics would then appear to be associated with both dopaminergic syndromes, initially parkinsonism, implicating dopamine underactivity, and eventually tardive dyskinesias, implicating dopamine overactivity. The explanation behind this apparent dichotomy relates to the fact that after chronic blockade, receptor function is altered. A large body of evidence demonstrates that after prolonged denervation, a receptor site becomes hypersensitive to ambient amounts of neurotransmitter exposure. This results in an enhanced response of the postsynaptic cell to neurotransmitter concentrations that previously led only to low rates of baseline firing. This phenomenon of denervation hypersensitivity has been extensively studied in the peripheral receptor site system and has been shown to apply to the dopaminergic striatal system as well. Ohye and associates (31) showed that after prolonged denervation the postsynaptic striatal cells fire with enhanced frequency in response to ambient dopamine that previously caused only low, baseline firing rates. A similar behavioral hypersensitivity can be seen in animals after chronic neuroleptic administration (32). The ultrastructural basis for this chronic hypersensitivity has been studied in detail, and it appears that hypersensitivity relates pathophysiologically to alterations in dopaminergic receptor site populations. After chronic neuroleptic administration to animals, there is an increase in the number of striatal dopamine receptors that clearly parallels the behavioral changes (32, 33). Analogous alterations may underlie the pathophysiology of tardive dyskinesia in man.

Dopamine turnover studies are consistent with the gradual development of denervation hypersensitivity. Cerebrospinal fluid levels of homovanillic acid, the major metabolite of dopamine, tend to increase acutely following the administration of neuroleptics (34). Within the first few weeks of treatment, this elevation tends to decrease so that after chronic treatment there is generally decreased turnover of dopamine (35–37).

The question of which dopamine receptor sites are sensitized is of central importance to an understanding of the pathogenesis and pathophysiology of tardive dyskinesias. If tardive dyskinesias result from prolonged blockade of the same dopaminergic receptors whose less chronic blockade leads to parkinsonism, some degree of parkinsonism would be a prerequisite for the subsequent occurrence of drug-induced tardive dyskinesias. Furthermore, these dyskinesias should occur in the same muscles, supplied by the same receptors that were involved in the parkinsonian manifestations. This is clearly not the case: tardive dyskinesias often occur in patients who have had no history or evidence on physical examination of drug-induced parkinsonism (29). Additionally, although patients with tardive dyskinesia tend to have fewer hypokinetic parkinsonian symptoms than neuroleptic-treated patients without tardive dyskinesia, case reports demonstrate that patients may suffer simultaneously from both tardive dyskinesia and drug-induced parkinsonism (38–40).

These observations suggest the possibility of more than one dopamine receptor site in the striatum. In fact, there is evidence from cellular recordings that at least two different dopamine receptor populations exist in the striatum. Dopamine receptors of the striatum have been demonstrated to respond to dopamine with facilitation or inhibition. Since the response of a receptor to a transmitter is a property of the receptor site and not of the transmitter, two different responses suggest two different receptors. When dopamine activates one type of receptor, the neuron is hyperpolarized or inhibited. These receptors could be called dopamine-inhibited receptors. The second type of receptor responds to dopamine stimulation with depolarization or facilitation and could be called the dopamine-facilitated receptors. Parkinsonism is usually related to decreased activity of dopamine at the dopamine-inhibited receptors.

It is of interest that although the neuroleptics block

both types of dopamine receptors, the degree of blockade is different for the two populations. The dopamine-facilitated neurons are blocked by levels of haloperidol or chlorpromazine that do not block the action of dopamine at dopamine-inhibited receptor sites. Only with larger doses of the neuroleptics are the dopamine-inhibited receptors also blocked (41). This observation, together with the observation that tardive dyskinesias can occur independently of drug-induced parkinsonism, suggests that the two disorders both relate to dopamine but to different receptor populations. One could visualize tardive dyskinesias as an abnormal hyperactive response of dopamine-facilitated receptors to dopamine, while parkinsonism relates to a lack of response of the dopamine-inhibited receptors to dopamine.

No large studies measuring receptor site populations in people with tardive dyskinesia have been performed, although receptor site measurements from brains of schizophrenic patients have been investigated. Owen and associates (42) demonstrated increased dopamine receptor sensitivity in both receptor numbers and affinity as measured by spiroperidol binding in the postmortem brains of schizophrenic patients. These biochemical changes were seen in patients who were receiving neuroleptic agents at the time of death, as well as in patients who were not receiving medication. However, those patients who were currently receiving medication demonstrated a greater degree of receptor site sensitivity. No information was reported on the incidence of tardive dyskinesia in these patients, so these data cannot be applied directly to the pathophysiology of tardive dyskinesia. However, dopamine receptor site sensitivity was increased in the caudate nucleus and putamen as well as in the nucleus accumbens of the limbic system. The former two basal ganglia are believed to be related to movements and motor disorders, while the latter limbic dopaminergic nucleus has been suggested to relate to the pathophysiology of psychosis.

A study by Lee and associates (43), which was similar to that of Owen and associates, reported increased haloperidol binding in the caudate nucleus, putamen, and nucleus accumbens of brains from patients with schizophrenia. Again, the prevalence of tardive dyskinesia in these patients was not discussed. Since ^{3}H-apomorphine binding was not altered in these brains, Nagy and associates (44) suggested that neuroleptic-induced alterations in receptor site binding in all three dopamine-rich areas were predominantly related to postsynaptic receptors.

A number of investigators have attempted to demonstrate dopaminergic hypersensitivity in patients with tardive dyskinesia by the use of various neuroendocrine tests. Neuroendocrine interest in relation to tardive dyskinesia and dopamine stems from the observation that there is a readily accessible and well-defined hypothalamine dopaminergic pathway that involves prolactin and human growth hormone (HGH) control (45–49). If tardive dyskinesia represents or is associated with a diffuse hypersensitive response of dopaminergic systems, neuroendocrine hypersensitivity might be expected. If a selective striatal alteration underlies the pathophysiology of tardive dyskinesia, however, necessary neuroendocrine changes in dopaminergic function would not be anticipated. Cohen and associates (50) reported normal prolactin response after exposure to thyrotropin-releasing factor in 4 schizophrenic patients with tardive dyskinesia and could demonstrate no hypothalamine dopaminergic supersensitivity. Similarly, the prolactin measurement in patients with tardive dyskinesia challenged with apomorphine showed no enhanced or hypersensitive response when compared with normal subjects (51). Growth hormone measurements after apomorphine challenge have suggested the same lack of hypothalamic hypersensitivity. One study (51) failed to show evidence of any difference between normal control subjects and patients with tardive dyskinesia, but a second study (52, 53), using the same apomorphine dose, reported that chronic schizophrenic patients with and without tardive dyskinesia showed slightly but not significantly lower growth hormone levels than control subjects. Although growth hormone responses in acute schizophrenia appeared higher than responses in control subjects, these responses cannot be viewed as relative to tardive dyskinesia because it is seen by definition after prolonged neuroleptic therapy for chronic disease. Neuroendocrine studies have therefore not revealed evidence of hypothalamic hypersensitivity in patients with tardive dyskinesia. These data would suggest that if the disorder relates to dopaminergic hypersensitivity, it is a selective hypersensitivity of certain receptor populations. Because of the clinical similarity of tardive dyskinesia to Huntington's chorea, the likely level of selective hypersensitivity would be the striatum. Studies of striatal receptor site hypersensitivity in nonschizophrenic patients with tardive dyskinesia have not yet been reported.

PHARMACOLOGIC THERAPY

With this pharmacologic background, one can consider therapeutic options in terms of the pathogenesis and pathophysiology of tardive dyskinesia. If the pathogenesis of the disorder relates to chronic dopaminergic receptor site blockade and the pathophysiology relates to the resultant denervation hypersensitivity, agents that interrupt this sequence would be of potential benefit. Reserpine acts by blocking the reuptake of dopamine, norepinephrine, and serotonin into the intraneuronal storage vesicles. In this way, reserpine depletes the brain of dopamine. Since it acts presynaptically, this drug would allow less endogenous

dopamine to be released onto the presumed hypersensitive dopamine receptor, thereby effecting a more normal dopaminergic homeostasis. Reserpine given in doses of 1–5 mg/day has been shown to reduce tardive dyskinesia in a number of clinical trials (54, 55). The potential side effects of hypotension and psychological depression must be monitored carefully. Reserpine-induced depression is infrequent in schizophrenic patients who do not have a history of affective disorder.

Jus and associates (56) recently reported treating tardive dyskinesia on the basis of a concept of slow desensitization of dopamine receptor sites. They hypothesized that because a long period of time is required to build up striatal hypersensitivity, a prolonged and slow decrease in neuroleptic blockade might resolve the problem. They treated 62 chronic schizophrenic patients who had tardive dyskinesia by a very slow (average period of 3.9 years), progressive, stepwise diminution of neuroleptic and antiparkinsonian medication. At the same time, they administered slowly increasing doses of reserpine or, when it was clinically necessary to control psychosis, a more sedating neuroleptic rather than the long-acting phenothiazines. Their long-term results were disappearance of tardive dyskinesia in 37% of the patients, improvement in 42%, and no effect in 21%. No patients demonstrated progression of abnormal movements. This long-term inpatient study has not yet been expanded to include outpatients.

Tetrabenazine, a synthetic benzoquinolizine that depletes monoamines by a mechanism similar to that of reserpine, is more rapid in onset, more selective for CNS activity, and has less hypotensive effects than reserpine. Given in doses of 100–300 mg/day, tetrabenazine has reduced or abolished tardive dyskinesia in several clinical trials, most of which, however, were short-term or lasted less than 6 months (57–60). Agents that deplete central dopaminergic stores serve as the mainstay of current therapy for tardive dyskinesia.

Formerly, tardive dyskinesias were often treated by increasing the dose of neuroleptics. This shortsighted treatment generally abates the abnormal movements but clearly is contraindicated. This method of therapy treats the pathophysiology of tardive dyskinesia but can aggravate the pathogenesis by further denervation and subsequent hypersensitivity. Epidemiological evidence shows a direct relationship between the incidence of tardive dyskinesia and the duration of neuroleptic therapy. In the individual patient, abnormal movements show a gradual progression over time, usually beginning with mild, localized lingual-facial-buccal dyskinesias and later becoming more severe and generalized. As neuroleptic therapy is prolonged, there is an increase in both the severity of abnormal movements and the number of body areas involved. As discussed in the section titled Epidemiology, the issue of age relative to prevalence of tardive dyskinesia can be difficult to separate from chronicity of medication. Nevertheless, it appears that the longer the pathogenesis persists, the more frequently and severely the physiology will be disrupted (21, 29, 54). For these reasons neuroleptics have no role in the routine treatment of tardive dyskinesias.

An additional therapeutic option is the manipulation of other neurotransmitters. There is a well-known and accepted balance between dopamine and acetylcholine in the striatum. Although Parkinson's disease relates primarily to dopamine alteration, the cholinergic system is known to modify the movements of the disease (29). Presumably, since dopamine is already decreased in the illness, decreasing the cholinergic influence as well would reestablish the relative neurotransmitter balance and reinstitute the former homeostasis at a different absolute level. Under the same premise, if tardive dyskinesias relate to an increase in dopaminergic effect, elevating the cholinergic effect would reestablish the former homeostasis, again at a new neurotransmitter level. In fact this appears to be the case: anticholinergic agents appear to aggravate the abnormal movements of tardive dyskinesias, and cholinergic agents may ameliorate them. Klawans and Rubovits (61) administered intravenous physostigmine to patients with tardive dyskinesias and demonstrated clear abatement of the abnormal movements. Although this study demonstrated the importance of neurotransmitter balance to the pathophysiology of tardive dyskinesias, this therapy has not been of practical benefit to patients because physostigmine cannot be given orally. Orally available precursors of acetylcholine include choline chloride and phosphatidylcholine (lecithin). In short-term studies (62), both agents have been reported to be useful in the control of tardive dyskinesias. Long-term controlled studies have not yet been conducted; these drugs remain experimental. Dimethylaminoethanol (deanol) was originally reported to be efficacious in the treatment of tardive dyskinesias, but more extensive studies have not corroborated this finding (63).

Using the same concept of dopaminergic-cholinergic antagonism relative to tardive dyskinesia, but with a focus on early or presymptomatic detection, Chouinard and associates (64) advocated the very short-term use of anticholinergics. They exposed patients who were receiving chronic neuroleptic therapy to small doses of anticholinergic drugs for a short period of time to see whether these doses uncovered or precipitated choreatic movements. If subclinical dyskinesias could be transiently unmasked by this alteration of dopaminergic-cholinergic balance, this precipitation would theoretically warn the clinician that striatal hypersensitivity was developing. Appropriate reduction of the neuroleptic or introduction of dopaminergic depleting agents could then be instituted as an early intervention. The efficacy of such treatment is unproven, and the distinction between this short-term provocation course of anticholinergic therapy and the

chronic exposure to anticholinergic drugs is essential. The latter course has been suggested, although not proven, to be associated with an enhanced chance of developing tardive dyskinesia.

Other agents have also been tried but remain unproven in the treatment of tardive dyskinesia:

1. Lithium. In two short-term studies mild improvement has been reported in tardive dyskinesia with lithium therapy (65, 66). Other studies reported no improvement or exacerbation (67, 68). Additionally, reemergence of tardive dyskinesia that had been quiescent for several years was seen in a patient when lithium therapy was introduced (69). The interaction of lithium with the dopaminergic system is not understood, but it is known that lithium accelerates synaptic reuptake of norepinephrine (*70*).

2. Baclofen (in patients who have to be maintained on neuroleptics). It has been suggested that baclofen, as a presumed γ-aminobutyric acid (GABA) agonist, affects the dopaminergic system at the level of the striatum or substantia nigra (71).

3. Levodopa. There are reports of amelioration following initial worsening of tardive dyskinesia with L-dopa (72).

4. Alpha-methyldopa. One report suggested amelioration of symptoms (73), but another indicated no change in tardive dyskinesia after methyldopa therapy (74).

5. Clonazepam. A benzodiazepine derivative, this drug is used in the treatment of seizure disorders. It has been reported to improve dyskinesia in 42 patients given 1–3 mg daily (75).

6. Manganese. The successful treatment of tardive dyskinesia has been reported in a small series of subjects given 60 mg/day of manganese chelate (76–78).

7. ECT. It has been suggested that ECT could increase the likelihood of the development of tardive dyskinesia in patients receiving neuroleptic drugs (2, 21, 79). These reports, however, lacked important historical and drug treatment information, so direct association could only be conjectured. In fact, a 1978 report (80) suggested that tardive dyskinesia may be ameliorated after ECT. The patient reportedly had had a stable degree of abnormal movement before ECT and showed a sudden dramatic and sustained improvement after the first three ECT treatments.

All of these agents were studied for a short period of time in small groups of patients. None of these modalities can be definitely recommended at this time.

RECOMMENDATIONS

The following principles should help to decrease the incidence of tardive dyskinesia:

1. Decrease the number of subjects at risk. Neuroleptics should be used only when clearly indicated and continued only when efficacy is clear.

2. Keep the daily dosage as low as possible.

3. Avoid the chronic use of anticholinergics if possible. Since anticholinergic agents clearly exacerbate already present tardive dyskinesia, it is possible that with chronic administration these drugs may alter the striatal neurochemical balance and potentiate the development of abnormal movements de novo (29).

4. Keep the duration of therapy as short as possible. Most schizophrenic patients are maintained on neuroleptics to control chronic symptoms or to prevent exacerbation. If used for the latter purpose it is quite possible that neuroleptics can be withdrawn for at least some period of time without a severe exacerbation. It is possible that such drug holidays might decrease the overall incidence of tardive dyskinesias. Data collected from animal studies suggest that drug-free periods should be at least one month long to be effective (32). The decision to withdraw neuroleptics must be individualized for each patient, and the relative morbidity of the abnormal movements must be weighed against the danger of a psychotic exacerbation.

5. Detect tardive dyskinesia early and quickly withdraw medication when possible.

6. In the event that neuroleptics are absolutely required, we tend to switch the medication to thioridazine. This practice is based on several considerations. First, there appears to be some relationship between drug-induced parkinsonism and tardive dyskinesia, and thioridazine has the lowest incidence of drug-induced parkinsonism of available neuroleptics. Evidence from animal experiments also suggests that some agents may be less likely to induce receptor hypersensitivity than others. In animals, thioridazine is a much weaker blocker of striatal dopamine receptors than other neuroleptics. Furthermore, in our laboratory we have been unable to produce receptor-site hypersensitivity measured either biochemically or behaviorally with chronic thioridazine but can easily produce this state with other phenothiazines and haloperidol in equivalent doses (81). There are no human data to establish a lower incidence of tardive dyskinesia with thioridazine, but, because of the above considerations, we feel that it is reasonable to substitute thioridazine in this situation. Clozapine, a neuroleptic not available in the United States, has the lowest incidence of associated parkinsonism and appears to be a more specific dopamine receptor blocker for the nucleus accumbens of the limbic system. In European studies, clozapine was reported to ameliorate tardive dyskinesia.

The low incidence of parkinsonism caused by thioridazine and clozapine has often been attributed to the ability of these agents to block central muscarinic receptors. The fact that these agents are both dopaminergic blockers and cholinergic blockers might suggest that they should have the highest likelihood of causing tardive dyskinesia. This is certainly not the case. No reports of clozapine-induced tardive dyskinesia have

yet appeared. From a variety of animal behavior studies it is clear that clozapine and thioridazine are not equivalent to another neuroleptic (e.g., haloperidol) plus an anticholinergic agent (72). The differences in incidence of parkinsonism may not be due solely to a neuroleptic's anticholinergic properties but may reflect a preferential ability to block specific striatal dopamine receptors.

With the exception of clozapine, the relative incidence of tardive dyskinesia with different neuroleptics is not definitely known; although thioridazine can cause tardive dyskinesia, we tend to feel safer using this drug when neuroleptic treatment is necessary.

PROGNOSIS

Shortly after neuroleptic withdrawal, tardive dyskinesia may worsen, presumably because of the better access of dopamine to striatal receptors. This exacerbation, however, is usually only a short-term effect. Tardive dyskinesias, in fact, are often reversible and may spontaneously remit following neuroleptic withdrawal. The earlier the symptoms are recognized and the drugs withdrawn, the better the prognosis for recovery (29). This is consistent with the view that tardive dyskinesia is a progressive disorder. The chance that tardive dyskinesias may become irreversible can be decreased by early detection and neuroleptic withdrawal; therefore, patients should be carefully examined for dyskinesias at frequent intervals. After the discontinuation of neuroleptic therapy, tardive dyskinesias can disappear, in some cases within one to two months. Larger series with more prolonged follow-up after the withdrawal of antipsychotic drugs have shown that patients can improve for up to two years and that mildly affected patients are more likely to experience complete remission (5, 6).

SUMMARY

The basic pathogenesis of tardive dyskinesia appears to relate to chronic pharmacologic denervation of specific dopaminergic receptor sites in the striatum. The pathophysiology of the disorder relates to the resultant denervation hypersensitivity. The mainstay of treatment includes withdrawal of neuroleptics when feasible and the use of dopamine-depleting agents. Enhancement of the striatal cholinergic input offers potential ancillary benefit to the alleviation of abnormal movements. The benefit of manipulating other neurotransmitters remains experimental. Treatment of tardive dyskinesia with neuroleptics themselves is clearly treatment with the presumed offending agent and should be avoided. This shortsighted therapy may temporarily abate the pathophysiology of the condition but serves to aggravate its pathogenesis.

The Manfred S. Guttmacher Award

The American Psychiatric Association invites applications for its biennial Manfred S. Guttmacher Award for 1981. The award is now given in odd-numbered years for outstanding contribution to the literature of forensic psychiatry in the form of a book, monograph, paper, or other work, including audio-visual presentations (films, etc.), submitted to or presented at any professional meeting or published during the period from December 1, 1978, to December 1, 1980. A plaque and an honorarium of $750 will be presented to the award recipient at the Convocation of Fellows at the 1981 APA annual meeting. Please note that the award recipient is now required to give a lecture at the annual meeting.

Anyone who wishes may apply by submitting five copies of the work as well as five abstracts to Robert L. Sadoff, M.D., Chairperson, Guttmacher Award Board, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Entries will be acknowledged but will not be returned.

Entries received by December 1, 1980, will be considered.

Opiate Use and Sexual Function

BY STEVEN M. MIRIN, M.D., ROGER E. MEYER, M.D., JACK H. MENDELSON, M.D., AND JAMES ELLINGBOE, M.D.

Although opiate addicts often equate the drug experience with sexual orgasm, diminished libido and impaired sexual performance are common sequelae of chronic use. Early clinical studies suggested that opiates may interfere with sex hormone secretion. The authors carried out three sequential studies which demonstrated that heroin use in man results in acute suppression of luteinizing hormone (LH) release from the pituitary followed by a secondary drop in plasma testosterone levels. The time course of these neuroendocrine events correlates well with the tension-reducing effects of heroin and suggests that drive reduction is an important component of opiate reinforcement.

The dramatic effects produced by an injection of heroin have been well described by both clinicians and users (1–4). A brief but very intense euphoria, followed by tension relief, seems to be the common denominator in the heroin experience. Chessick (5) called this sequence of events the "pharmacogenic orgasm," and addicts themselves often describe it in sexual terms. In the case of intravenous heroin the immediate postinjection "rush" is frequently equated to sexual orgasm, and subsequent feelings of tension relief and relaxation have been likened to "being wrapped in warm cotton," "returning to the womb," or similar allusions to warmth, security, and being cared for.

Presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12–18, 1979. Received May 21, 1979; accepted July 26, 1979.

In contrast to these retrospective accounts of the drug experience, untreated male heroin addicts and patients in methadone maintenance programs report that decreased interest in sex, impotence, and delayed ejaculation are common problems during opiate use (6–10), and opiate withdrawal has been associated with renewed sexual interest and premature ejaculation (11) in many patients. As a result of these observations, interest in the sexual sequelae of opiate use has shifted from an emphasis on intrapsychic factors to the study of the hormonal correlates of drug administration. In this context, a series of clinical and laboratory studies have explored the effects of opiates on the hypothalamic-pituitary-gonadal axis. This paper reviews a number of these studies in man, including some recent data from our laboratory. We will attempt to reconcile the curious dichotomy between the acute reinforcing effects of opiates, as expressed in the language of sexual gratification, and the neuroendocrine sequelae of chronic use, which appear to be somewhat less gratifying.

EFFECTS OF CHRONIC OPIATE USE ON PITUITARY-GONADAL FUNCTION IN MAN

Early clinical studies (12–14) of the effects of opiate use on pituitary-gonadal function were hampered by a variety of methodologic problems. In outpatient studies it was difficult to control for the amount of prior drug use across subjects as well as the amount of time elapsed between drug administration and hormonal measurements. Furthermore the pituitary gonadotropins and testosterone are secreted in a pulsatile fashion; thus even individuals with normal gonadal function have considerable moment-to-moment variation in the mean plasma level of these hormones (15). Consequently the infrequent plasma sampling (i.e., once or twice per day) that characterized earlier clinical studies made it difficult to accurately assess drug-induced changes in the episodic secretory pattern of these hormones. Finally, most early studies lacked the methodology for direct measurement of pituitary and gonadal hormones. More recent studies (16–21) have used modern radioimmunoassay techniques for the quantitation of these hormones.

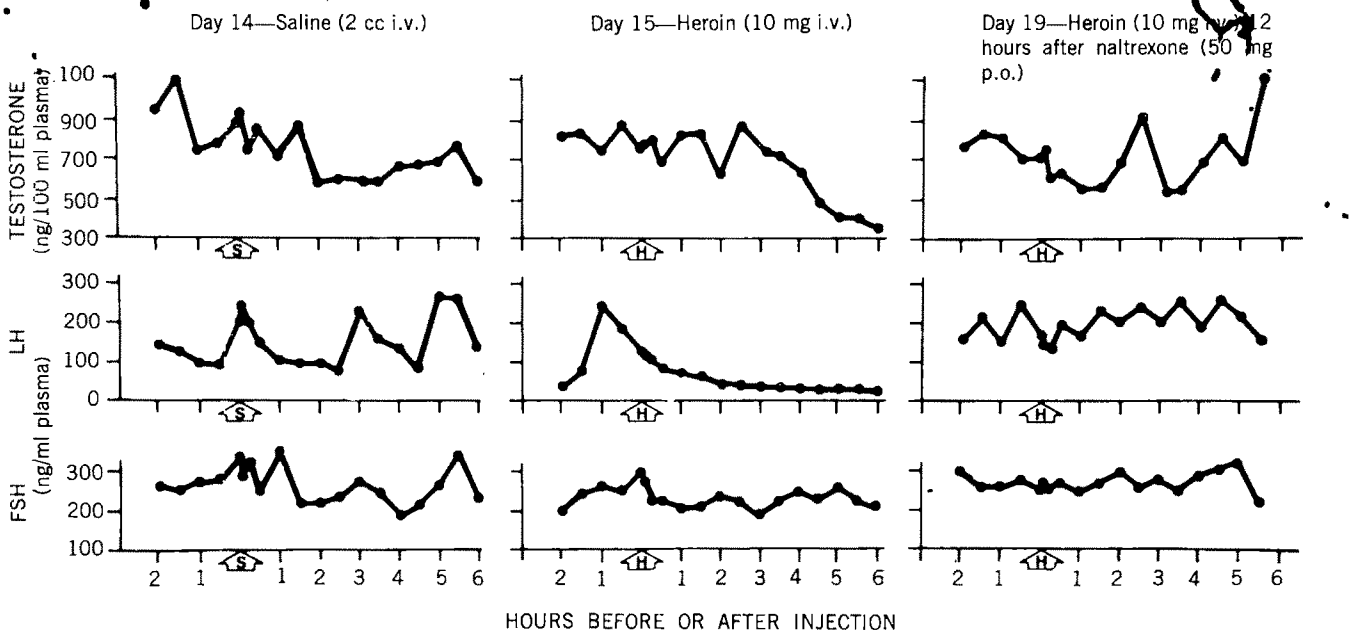
In the face of these methodologic difficulties it is not surprising that the results of earlier studies often

proved contradictory. Nonetheless some general trends can be discerned. Azizi and associates (12) found lower than normal levels of serum testosterone in 8 of 16 heroin addicts and 2 of 6 chronic methadone users, although levels of estradiol, luteinizing hormone (LH), and follicle-stimulating hormone (FSH) were not consistently altered in these subjects. Cushman (13) also reported no change in LH secretion among active heroin users and abstinent former addicts. In a subsequent study (14), however, high dose methadone users (>40 mg/day) and some untreated heroin addicts had low plasma testosterone levels when compared with nonaddict controls; they also reported a variety of sexual problems during active drug use. In another study, Martin and associates (16) observed decreased plasma LH and FSH levels in 5 men maintained on 100 mg of methadone per day, but after 1 month of abstinence their gonadotropin levels were actually increased over predrug levels. In 1975 Mendelson and associates (17) studied a group of patients on heroin maintenance who, after receiving fixed doses of heroin at fixed intervals, reported diminished interest in sex and potency problems and had a significant decrease in plasma testosterone compared with normal nonaddict control subjects. These investigators also found lower than normal levels of plasma testosterone in untreated heroin addicts who had a recent history of heavy use and in patients on high dose (80–150 mg/day) methadone maintenance. In a subsequent study (18) Mendelson and Mello found diminished plasma testosterone levels in a group of chronic heroin users; after 1 month of abstinence, however, their testosterone levels were within the normal range for adult males. Finally, Cicero and associates (19) compared 29 patients maintained on methadone (mean dose=67 mg/day) with 16 active heroin addicts and 43 drug-free controls and found that methadone-treated patients had markedly impaired function of their secondary sex organs and significantly lower levels of serum testosterone compared with the other two groups.

Over the last 4 years our research group has carried out a series of studies on the acute and chronic effects of opiate administration on pituitary-gonadal function, attempting to avoid some of the methodologic problems found in earlier studies. As part of a multidisciplinary research project, detoxified heroin addicts were admitted to a four-bed research ward and allowed to self-administer intravenous heroin under a variety of experimental conditions. Their informed consent was obtained after the procedures had been fully explained. In all studies individual subjects or groups of subjects served as their own controls. Heroin dosage and the timing of plasma sampling for hormonal determinations was controlled by the experimenters. Since these studies, including the methods used to quantitate plasma levels of testosterone and pituitary gonadotropins, have been reported elsewhere (20–22), we will only summarize our findings here. The designs of our three experiments are presented in table 1.

Experiment 1

In our first study (20) we assessed the effects of chronic heroin use on plasma testosterone levels in 10 detoxified addicts, who were permitted self-regulated access to increasing doses of intravenous heroin over a 10-day period. Blood samples for plasma testosterone determinations were collected each morning at 8 a.m., approximately 6 hours after the previous heroin injection. The acute hormonal response to heroin or its effect on pituitary gonadotropins was not assessed in this first study. During study period 2, as the total daily dose of heroin increased, plasma testosterone levels fell. When the preceding day's heroin dose was between 45 and 60 mg, testosterone levels fell below 400 ng/100 ml, significantly lower than during study period 1, when subjects were drug-free ($p<.02$, matched t test). Following a period of methadone detoxification (study period 3), testosterone secretion gradually returned to predrug levels.



Experiment 2

In our second study (21) we sought to measure the acute effects of heroin on the pituitary-gonadal axis. After 2 weeks on a drug-free regimen and 1 saline control day (periods 1 and 2), 2 detoxified male addicts were given 10 mg i.v. of heroin. The 2 subjects had very similar hormonal responses. As illustrated in figure 1 (subject 1) the result was an almost immediate fall in the level of plasma LH. This acute response was not observed when subjects received saline, nor did it occur when subjects were pretreated with naltrexone, a narcotic antagonist with few agonistic effects of its own (23). In both subjects LH suppression was still observed 6 hours after heroin injection, although some recovery in LH secretion was noted in 1 subject. Interestingly, pretreatment with naltrexone, 12 hours before heroin administration, resulted in a mean 50% rise in plasma LH levels compared with levels on the saline control day. The number and frequency of LH secretory pulses also increased following naltrexone administration. Despite the rise in LH, however, testosterone secretion was only marginally increased in 1 subject and unaffected in the other. In none of the experimental conditions was FSH affected.

Experiment 3

In our third study (22) we examined the acute and chronic effects of unblocked and naltrexone-blocked heroin use on the pituitary-gonadal axis. Our goals were to replicate our findings from experiment 2 in more subjects and to better assess the time course of the acute suppressant effect of heroin on LH and testosterone. We also wanted to determine whether chronic heroin and/or naltrexone use altered the acute response to heroin. There were three different double-

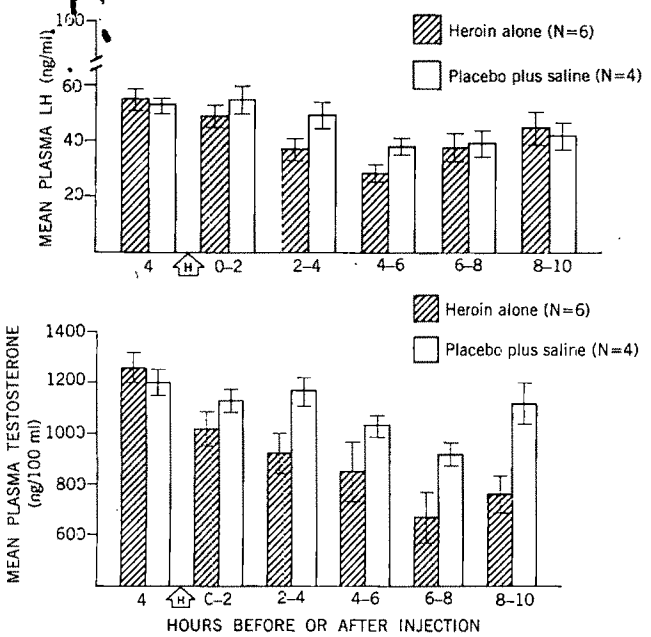
Plasma Testosterone, LH, and FSH Levels Before and After Injection of Saline, Heroin, and Heroin Preceded by Naltrexone (22)[a]

[a]All injections were given at 10:00 a.m.

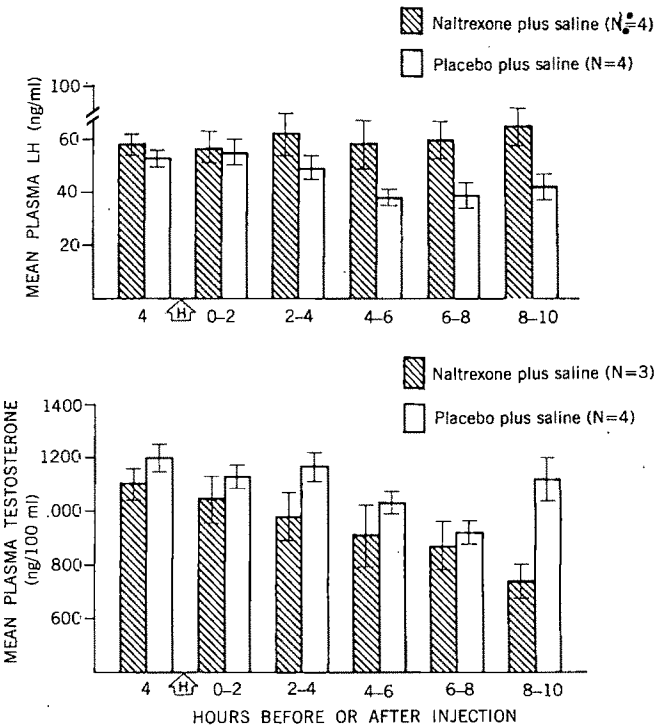
TABLE 1
Three Studies of the Acute and Chronic Effects of Opiate Administration on Pituitary-Gonadal Function (22)



Study Period	Experiment 1 (N=10)		Experiment 2 (N=2)		Experiment 3 (N=8)	
	Day	Condition	Day	Condition	Day	Condition
1	1-7	Drug-free	1-13	Drug-free	1-7	Drug-free
2	8-17	Heroin[a]	14 (10:00 a.m.)	Saline, 2 ml i.v.	7 (2 p.m.)	Heroin, 10 mg i.v. (unblocked)
3	18-24	Methadone detoxification	15 (10:00 a.m.)	Heroin, 10 mg i.v. (unblocked)	10 (6 p.m.) 10 (10 p.m.)	Naloxone, 0.4 mg i.v. Naltrexone, 50 mg i.v., or placebo
4	25-34	Drug-free	18 (6 p.m.)	Naloxone, 0.4 mg i.v. Naltrexone, 50 mg p.o.	11 (2 p.m.)	Saline, 2 ml i.v., plus naltrexone, 50 mg p.o., or placebo
5	35-36	Narcotic antagonist	19 (10 a.m.)	Heroin, 10 mg i.v. (blocked)	12-23 (8 a.m.)	Naltrexone, 50 mg p.o., or placebo
6	37-46	Narcotic antagonist plus heroin	20-25	Naltrexone, 50 mg p.o.	13 (10 a.m.) to 23 (8 a.m.)	Heroin[a]
7	47-60	Narcotic antagonist alone			23 (2 p.m.)	Heroin, 10 mg i.v.

[a]Heroin was available any time but not more often than every 2 hours to prevent drug accumulation. The allowable intravenous dose escalated from 0.5 mg on day 8 to 5 mg on day 18 to accommodate tolerance. By waiting 4 hours the subject could double the allowable dose; after 6 hours he could triple it. Waiting longer than 6 hours resulted in no further increment. Subjects had the option of not self-administering heroin or of taking less than the allowable dose.

blind conditions. After 6 drug-free days 8 subjects received an injection of 10 mg of heroin; 4 days later all subjects received intravenous saline 12 hours after pretreatment with either naltrexone (N=4) or an equivalent volume of placebo (N=4). After 10 days of access to heroin (see table 1) naltrexone-treated and placebo-treated subjects received another 10-mg dose of heroin. Plasma levels of LH and testosterone were determined on integrated blood samples collected at 30-minute intervals from 4 hours before to 10 hours after each test injection. Blood samples were collected with the use of a constant exfusion pump; thus hormonal levels are expressed as the mean value for each 30-minute collection period.



In general, pooled data for these subjects were consistent with our earlier findings. As illustrated in the top panel of figure 2 heroin-induced suppression of LH secretion was first evident 2–4 hours and was greatest 4–6 hours after unblocked heroin injection. In this study the degree of LH suppression was not as great as that observed previously. Since some subjects were given heroin after only 1 week on the research ward, compared with a 2-week drug-free period in the earlier studies, some may have been partially tolerant to the

FIGURE 2
Effects of Heroin (10 mg i.v.) Versus Isotonic Saline on Plasma Levels of LH and Testosterone (22)[a]

[a]In the unblocked heroin condition, accurate data were obtained in 6 of the 8 subjects; all injections were given at 2:00 p.m.

FIGURE 3
Effects of Heroin (10 mg i.v.) Versus Isotonic Saline on Plasma Levels of LH and Testosterone on Day 11 (Before Heroin Phase) (22)[a]

[a]Accurate data on plasma testosterone levels were obtained in 3 of the 4 naltrexone-treated subjects; all injections were given at 2:00 p.m.

effects of heroin on LH. The maximum decline in plasma testosterone occurred 6–8 hours after heroin injection (bottom panel figure 2). As in experiment 2, some recovery in LH secretion was noted 6 hours after heroin injection and was followed shortly by a rise in plasma testosterone.

As illustrated in figure 3 measurement of plasma LH in subjects on naltrexone or placebo also replicated our earlier finding—the naltrexone-treated subjects had consistently higher levels of LH, but their plasma testosterone levels were no different from the placebo-treated group. After 10 days of unblocked heroin use, there was some indication that tolerance developed to the drug's acute suppressant effect on LH and testosterone, but the timing of drug administration and blood sampling in this study did not allow for accurate assessment of this question. Investigation of tolerance development would require that the hormonal response to a single dose of heroin be measured on several consecutive days during a sustained period of fixed-dose, fixed-interval drug administration.

DISCUSSION

Opiate Effects on Sexual Functioning

There is ample clinical evidence that sexual drive and performance are diminished in male opiate addicts (6–11). Only recently, however, has a link been forged between these clinical observations and opiate-induced changes in the hypothalamic-pituitary-gonadal axis. Recent animal studies (24–26) and our data in man (21, 22) suggest that a prominent neuroendocrine effect of opiate administration is suppression of plasma LH secretion followed by a secondary decline in testosterone production. If the primary effect of heroin were on testosterone biosynthesis or metabolism, we would have expected a more rapid fall in plasma testosterone followed by an increase in plasma LH. This is the normal response to a fall in plasma testosterone and results from disinhibition of the tonic control exerted by testosterone on the release of luteinizing hormone releasing factor (LRF) from the hypothalamus. LRF is released in episodic bursts and, in turn, controls LH secretion from the pituitary (27–29). That acute heroin administration appears to completely inhibit episodic LH secretory pulses suggests a central effect on the release of hypothalamic LRF. In laboratory animals the regulation of LH (via LRF secretion) has been localized to ventral and medial areas of the hypothalamus (30), a region that also possesses numerous opiate receptor binding sites and a high concentration of endogenous opiate peptides (31).

In our studies pretreatment with a narcotic antagonist (naltrexone) not only blocked heroin-mediated suppression of LH release but actually increased the frequency of LH secretory bursts from the pituitary. As a result mean plasma LH levels were elevated in naltrexone-treated subjects. This finding can best be

explained in light of our advancing knowledge about the role of endogenous opioids (i.e., endorphins) and opiate receptors in the regulation of hormonal output. The endogenous opioids may play an inhibitory role in the normal regulation of LH secretion (32), and this inhibitory effect may be blocked by administration of a narcotic antagonist. One could also explain naltrexone's stimulation of LH release as a hormonal concomitant of precipitated abstinence; however, a recent double-blind study by Ellingboe and associates (33) revealed that naltrexone given to nonaddicts increased mean plasma LH levels by 50% over baseline, which again suggests the involvement of a hypothalamic-pituitary mechanism.

Finally, our studies indicated little effect of either heroin or naltrexone on plasma FSH secretion. Cicero and associates (24, 25) found the same dichotomous response to opiates in the rat. Their data suggest that those areas of the hypothalamus which influence the synthesis and release of pituitary LH may be more sensitive to the effects of opiates than those which mediate FSH levels. Although one study has demonstrated anatomic separation of the centers that control LH and FSH release in animals (34), there is no clear evidence of such a separation in man. Indeed, the decapeptide (LRF) that regulates pituitary release of LH probably plays a role in FSH release as well, although the pituitary response is usually of lower magnitude.

Correlation of Endocrine Changes with Mood States

Addicts often cite the acute euphorigenic and tension-relieving effects of opioids as important factors in the decision to initiate and maintain drug use. At the same time, laboratory studies of opiate use in man have consistently demonstrated that chronic administration of these substances is associated with the development of increased psychopathology and dysphoric mood states (35–38). Recently we have attempted to relate such events to changes in brain catecholamine levels (39), but the observed clinical phenomena are the result of many factors, including expectancy and the setting in which the data are gathered.

At present there are also sufficient data to explain the brief (30–60 seconds) but intensely pleasurable rush that immediately follows intravenous heroin administration. The mechanism most likely involves massive release of catecholamines at both central and peripheral sites. The rush is followed by a less intense, but more sustained, period of relaxation and tension relief lasting 2–4 hours. The strength and duration of this effect are influenced by the dose administered, the level of plasma morphine achieved (heroin [diacetylmorphine] is almost immediately converted to morphine by the liver), the rate of elimination of the drug, the degree of tolerance developed, and the conditioned and unconditioned stimulus properties of the environment (39–40). The time course of this effect closely parallels, and may be related to, the acute effects of heroin on neuroendocrine function—specifically, the acute suppression of LH release followed by a secondary fall in plasma testosterone. Indeed, heroin acts much like the antiandrogen compound cyproterone acetate, which suppresses the release of pituitary gonadotropins (especially LH), lowers testosterone levels, and reduces both sexual drive and performance (41). In low doses acute administration of cyproterone acetate alters the computerized electroencephalogram in a fashion similar to that of the tricyclic antidepressants; larger doses produce a profile much like the benzodiazepine anxiolytics (42). On the other hand, as with heroin, chronic administration of cyproterone acetate has been reported to produce apathy, restlessness, and depression (41). The similarity of these data to our observations in heroin users is striking. In contrast, acute administration of naltrexone raises LH levels in detoxified opiate addicts (21) and normal volunteers (33), while producing a dysphoric mood state and increased sexual drive (43).

Although no direct link has been demonstrated between sex hormone changes and temporally related alterations in mood, our data on the acute effects of heroin suggest a drive reduction model of opiate reinforcement, in which the drug acts as an antianxiety agent and reduces sexual drive and tension. Whether this effect is a direct consequence of acute suppression of LH and testosterone or is mediated through the same hypothalamic mechanisms that control LH release (i.e., alterations in catecholamine systems) is unclear. It is also possible that changes in other hormone systems (e.g., the hypothalamic-pituitary-adrenal axis) may also play a role.

With repeated heroin use, tolerance develops to the drug's acute positive effects on mood (38) and subjects manifest increasing apathy, irritability, depression, and social withdrawal (38, 40). This may be related to the development of tolerance to its acute suppressant effect on LH and testosterone or to alterations in the catecholamine systems that control mood and hormonal output. Nonetheless, chronic heroin users and patients on high doses of methadone still have low circulating levels of testosterone, a condition common to other groups who manifest high levels of anxiety and depression, such as soldiers under stress (44, 45), intoxicated alcoholics (46), and monkeys who have recently lost status (47). Although there are data which suggest that testosterone may exert a mood-elevating effect in man (48, 49), Sachar and associates (50) found no correlation between testosterone levels and mood.

The relationship between the subjective effects of opiate use and the neuroendocrine events that accompany these phenomena is still unclear. We do not yet understand the role of endorphins in the regulation of sex hormone secretion, the mediation of drive states, and the regulation of mood. We hope that future research will help to clarify these issues.

Lithium Response in Good Prognosis Schizophrenia

BY JACK HIRSCHOWITZ, M.D., REGINA CASPER, M.D., DAVID L. GARVER, M.D., AND SIDNEY CHANG, M.D.

The authors report the results of a 2-week lithium trial using 31 patients meeting Research Diagnostic Criteria for schizophrenia or schizoaffective disorder who were also diagnosed according to DSM-III *criteria. One-third of the patients showed reduction of their schizophrenic-like symptoms during the lithium trial. Seven of the 9 responders (78%) met* DSM-III *criteria not for schizophrenia but for a schizophreniform disorder. Such patients also met McCabe and associates' criteria for good prognosis schizophrenia. This study lends further support to the growing body of evidence which suggests that schizophreniform disorder and good prognosis schizophrenia may be affective disorders with atypical schizophrenic-like features. The authors cautiously suggest that a lithium trial may be indicated in this subgroup of patients.*

There has been growing interest in the use of lithium in the schizophrenias, but reports on its efficacy in schizophrenic patients are conflicting (1, 2). One of the most patent difficulties in evaluating treatment results is the inconsistency in the diagnostic criteria used for schizophrenia and the so-called schizoaffective disorders. Alexander and associates (3), in a recently published study using the Research Diagnostic Criteria (RDC) of Spitzer and associates (4), demonstrated that some schizophrenic-like patients appear to respond to lithium; however, they were unable to find any RDC parameters that would discriminate responders. The present study is an attempt to identify diagnostically a subgroup of schizophrenic-like patients for whom a lithium trial is indicated. It is also, to our knowledge, the first study that has examined lithium response in relation to the *DSM-III* criteria for schizophreniform versus schizophrenic disorders.

Presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12–18, 1979. Received Aug. 13, 1979; revised Feb. 4, 1980; accepted Feb. 22, 1980.

METHOD

Consecutive patients with a suspected diagnosis of schizophrenia were admitted to the psychobiology treatment unit. Only patients who then met the RDC for schizophrenia and schizoaffective disorder were admitted to the study. To meet the RDC, patients must have had at least two symptoms from a list that includes specific types of delusions, hallucinations, and thought disorder. The illness must not have been evidence of coarse brain disease, medical illness, or significant alcohol or drug abuse (5).

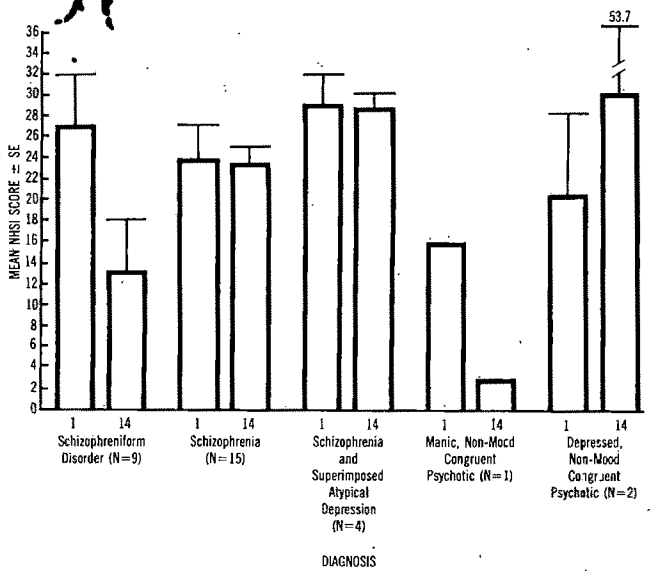
Study patients underwent a 2-week washout period. During the second week the baseline data, including the full Schedule for Affective Disorders and Schizophrenia (SADS), were collected. The SADS, developed by Spitzer and colleagues, is a standard interview that documents symptoms, both at the time of the interview and at the time during which the illness was at its worst for this episode, time course of illness, previous illnesses or episodes, and premorbid functioning. After completion of the SADS, a series of formal diagnoses was made for each patient by the research physicians according to the RDC (5), *DSM-III*, the good versus poor prognosis criteria of McCabe and associates (6, 7), and Taylor and Abrams' criteria for mania (8, 9). McCabe and associates' criteria emphasize differences in degree of recovery from previous episodes of major psychiatric illness. Taylor and Abrams' criteria for mania reclassified patients who met criteria for schizoaffective illness as manic on the basis of the presence of all four of the following features: hyperactivity; rapid or pressured speech; euphoric, expansive, or irritable mood with a broad affect; and absence of concurrent medical illness. Patients were excluded from the study if they met Taylor and Abrams' criteria for mania, resulting in a residual group of schizophrenic-like patients who would not typically be diagnosed as having mania or a variation of mania. Patients whose schizophrenic symptoms were mild as reflected by an initial modified New Haven Schizophrenia Index (NHSI) score of less than 12 (out of a possible score of 80) were also excluded.

because small changes in ratable symptoms in such patients could not be reliably estimated without artificial magnification and distortion of individual results.

Beginning during the second drug-free week, the Serial Modified NHSI was scored twice weekly by rating teams standardized with the instrument. The raters included a psychologist and social worker who did not participate in the original diagnostic workup. This instrument rates on a scale of 0–5, depending on the degree of severity, delusions, hallucinations, thought disorder (including bizarre reasoning, looseness or overinclusion, autism, and concreteness), disturbances of affect, confusion, paranoid ideation, and catatonic symptoms. The NHSI was originally designed for diagnostic purposes (10), but has been modified for use as a change rating scale (11, 12). The scale uses explicit criteria for identifying specific symptoms and rating their intensity. Furthermore, it has been used to rate psychotic thought disturbance at intervals of 20 minutes (13). The usefulness of the scale has been demonstrated in several studies that show relationships between blood levels of antipsychotic drugs and patient response (11, 12, 14). In addition to the NHSI, the Affective Disorders Rating Scale was scored twice weekly by a team of nurse-raters. Our interest in this latter instrument was primarily in the mania and depression scores.

On day 1 of the lithium trial, patients began a regimen of 1200 mg daily of lithium carbonate, which increased each second day by 300 mg until either toxicity developed or a plasma lithium level of 1.4 mEq/liter had been achieved. An attempt was made to maintain patients at between 1.1 and 1.4 mEq/liter. Blood levels of lithium were monitored three times weekly during the 2-week trial.

The absolute and percentage change during lithium treatment (days 1–14) was computed for each patient from the least squares linear regression of the biweekly NHSI (schizophrenic symptoms) and the Affective Disorders Rating Scale (affective symptoms scores). Improvement of greater than 30% on the NHSI was defined as response during the 2-week lithium trial. Analysis of variance was used to compare results among subgroups. Fisher's exact test was used to compare the relationships between lithium response and the diagnostic categories of the RDC, *DSM-III*, and McCabe and associates (6, 7).



RESULTS

Of the 42 patients who entered the study, 11 were dropped before its completion. Two chronic paranoid schizophrenic patients were dropped because they had incorporated the medication into their delusional system and did not take medication on a regular basis, which resulted in fluctuating blood levels of medication. Five patients required more conventional antipsychotic drugs during the washout and baseline periods. Of these 5 patients, 3 had been symptomatic less than 6 months. Four patients required antipsychotic medication in addition to lithium during the early phase of drug treatment. All 4 had been ill for less than 6 months; all of them were subsequently discharged on lithium therapy, 2 of them on lithium alone. Such dropouts indicate that the study has been somewhat selective; we report data on only those patients who could tolerate 4 weeks without conventional antipsychotic drugs. Some of our most disturbed schizophrenic-like patients did not have the opportunity of a lithium trial.

The mean age of the 31 patients who completed the 2-week lithium trial was 25.3±1.1 years. There were 21 male patients and 10 female patients. During the baseline week the mean percentage change of schizophrenic symptomatology on the NHSI was 2.7±7.5%, which suggests that minimal change in symptoms occurred during the week before the initiation of lithium.

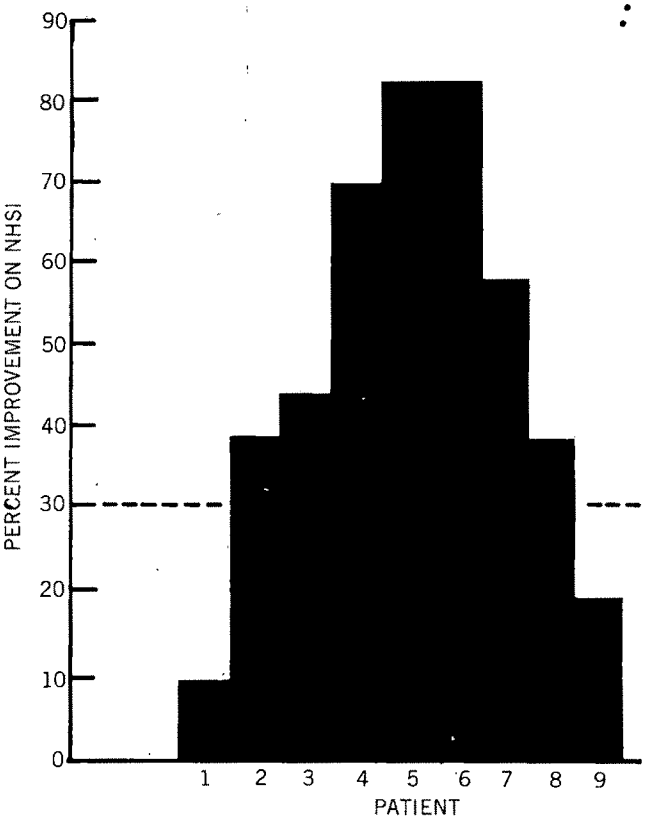


Figure 1 identifies the patients according to *DSM-III* diagnosis and shows mean NHSI scores for each diagnostic group on days 1 and 14 of the lithium trial. Nine patients met the *DSM-III* criteria for schizophreniform disorder. Schizophreniform disorder has the essential features of schizophrenia, except the duration is less than 6 months. This group showed a mean improvement score of 13 points, that is, a 49.7% reduction of baseline NHSI scores. The within-group variance of such reduction of NHSI scores for the schizophreniform group was significantly less than the total variance for all the groups ($p<.01$). Fifteen patients met the *DSM-III* criteria for schizophrenia. These criteria are essentially the same as those of the RDC, except that the illness must have lasted for at least 6 months. The mean improvement for this group between days 1 and 14 was 1 point on the NHSI, that is, a 0.6% reduction of baseline NHSI scores. Four patients met the *DSM-III* criteria for schizophrenia with a superimposed atypical depression. They met *DSM-III* criteria for schizophrenia but had for a short period of time a superimposed depressive syndrome. Once again there was minimal change for this group, with a mean deterioration of 1 point on the NHSI—that is, a 1.5% increase of baseline NHSI scores. The last two categories comprised 3 patients who although meeting the RDC for entrance into the study were rediagnosed according to *DSM-III* as having an affective illness rather than schizophrenia or schizoaffective disorders. These patients had so-called "non-mood congruent psychotic symptoms" superimposed on a major affective illness. Non-mood congruent psychotic symptoms refers to those symptoms which are schizophrenic-like but the dominant syndrome is an affective one. One patient was rediagnosed according to *DSM-III* as manic, non-mood congruent; he responded dramatically to lithium. The 2 remaining patients were depressed, non-mood congruent; one of them showed a non-

FIGURE 1

FIGURE 2
Individual Percentage Improvement on the New Haven Schizophrenia Index (NHSI) in 9 Schizophreniform Patients Between Days 1 and 14 of Lithium Treatment

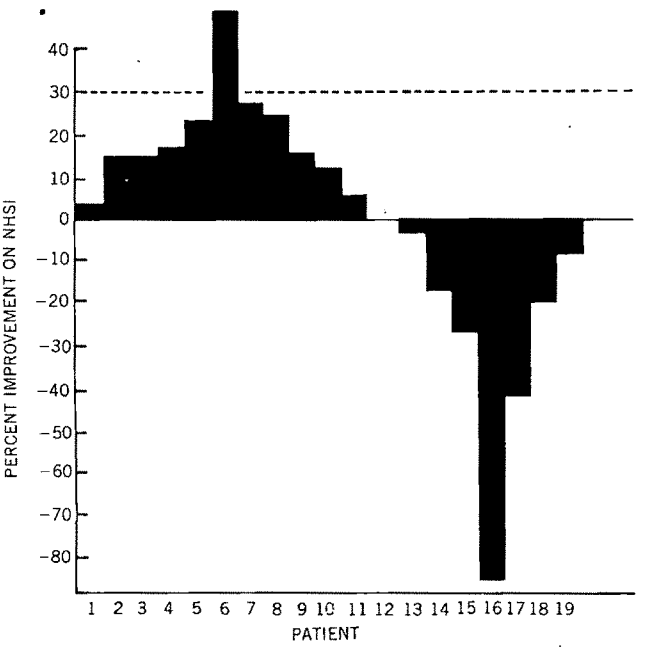
significant improvement during the lithium trial, and the other showed a marked deterioration during the lithium trial.

Figure 2 illustrates the percentage change on the NHSI for each of the 9 patients given a diagnosis of schizophreniform disorder by *DSM-III* criteria. Seven of these patients showed a greater than 30% improvement on the NHSI during the 2-week lithium trial. All 9 were discharged on lithium therapy; 2 patients required neuroleptic medication in addition because of residual schizophrenic-like symptoms that appeared to persist with lithium alone. One patient who made an 8% improvement during the 2-week lithium trial subsequently improved dramatically during the third week while receiving lithium alone and was also discharged on lithium therapy.

Figure 3 illustrates the percentage change on the NHSI for each of the 19 patients diagnosed as having schizophrenia or schizophrenia with a superimposed atypical depression. Only 1 of these patients showed a greater than 30% improvement on the NHSI.

It is interesting to examine the relationship among the *DSM-III* diagnoses, the RDC diagnoses, and McCabe and associates' good versus poor prognosis groups. The 9 patients who met *DSM-III* criteria for schizophreniform disorder included 5 RDC schizophrenic patients and 4 RDC schizoaffective patients, 1 schizoaffective-manic and 3 schizoaffective-depressed patients. All *DSM-III* schizophreniform patients met McCabe and associates' criteria for good prognosis schizophrenia.

All 15 of the *DSM-III* schizophrenic patients also met the RDC for schizophrenia; all similarly met McCabe and associates' criteria for schizophrenia of poor prognosis.



The 4 patients meeting *DSM-III* criteria for schizophrenia with superimposed atypical depression met RDC criteria for schizoaffective depressed and were poor prognosis schizophrenic patients according to the criteria of McCabe and associates.

There were no *DSM-III* schizoaffective patients in this sample of 31 schizophrenic-like subjects.

The single *DSM-III* manic, non-mood congruent psychotic patient was an RDC schizoaffective, manic patient and a good prognosis schizophrenic patient according to McCabe and associates' criteria. The 2 *DSM-III* depressed, non-mood congruent psychotic patients were RDC schizoaffective, depressed patients and poor prognosis schizophrenic patients according to McCabe and associates' criteria.

With respect to therapeutic response during the 2-week lithium trial, within the *DSM-III* groups (excluding the affective non-mood congruent groups) 7 of 8 lithium-responding patients could be identified as members of the schizophreniform group, while 17 of 20 lithium-nonresponding patients could be identified as having schizophrenia or schizophrenia with super-

FIGURE 3
Individual Percentage Improvement on the New Haven Schizophrenia Index (NHSI) in 19 Patients with Schizophrenia and Schizophrenia with Superimposed Atypical Depression

imposed atypical depression ($p<.0005$, Fisher exact probability test).

Using the RDC for schizophrenia or schizoaffective disorder to preselect patients for the subsequent good versus poor prognosis classification of McCabe and associates, 8 of 10 good prognosis patients responded during the lithium trial, while 20 of 21 poor prognosis patients had no response during a similar lithium trial ($p<.0001$, Fisher exact probability test, two-tailed).

In contrast, RDC diagnosis of schizophrenia versus schizoaffective disorder did not differentiate between lithium responders and nonresponders. Five of 20 schizophrenic patients responded during the lithium trial; four of 11 schizoaffective patients similarly responded ($p>.5$, Fisher exact probability test, two-tailed).

The depression and mania subscales of the Affective Disorders Rating Scale were examined for 6 of the 9 *DSM-III* schizophreniform patients who completed the lithium trial in order to determine whether the antipsychotic effect of lithium in this group of patients was paralleled by a reduction in depression or mania ratings. No relationship was found between changes in the NHSI and changes in either the mania or depression subscores of the Affective Disorders Rating Scale during the lithium trial.

DISCUSSION

Beginning with a group of 31 patients who met the RDC for schizophrenia or schizoaffective disorder, we rediagnosed such patients according to *DSM-III* and McCabe and associates' good versus poor prognosis criteria for schizophrenia. Each of the patients received a 2-week trial of lithium, with plasma levels greater than 1.0 mEq/liter. Good prognosis schizophrenic patients (McCabe and associates) and patients with schizophreniform disorder (*DSM-III*) showed amelioration of their schizophrenic-like symptoms during the lithium trial. More common diagnostic criteria, based primarily on symptoms, such as the schizophrenia versus schizoaffective distinctions on the RDC, failed to differentiate lithium responders from nonresponders.

Several studies reviewing the characteristics of nondeteriorating schizophrenia and schizoaffective syndromes have elicited the common features of these disorders (14–21). These include good premorbid adjustment, the presence of a precipitating event, acute onset, presence of confusion or excitement, and an affective heredity. In their recent review Pope and Lipinski (22) suggested that affective-like course (exacerbation and full remission) of schizophrenic-like symptoms and family history of affective disorders may differentiate those patients who may benefit from lithium better than symptoms do. Our work supports the finding that acute onset and good premorbid adjustment are indicators of lithium response, but we were not able to find that affective symptoms are in any way related. In addition, we found that *DSM-III*, which is a clinical diagnostic instrument, discriminated better than the RDC, which is a research diagnostic instrument, in predicting lithium response.

Thus there appears to be a growing body of evidence which suggests that schizophrenia of good prognosis and a substantial number of the schizophrenia disorders may be lithium-responsive affective disorders masquerading phenomenologically as schizophrenic-like illnesses. Our data support this notion and suggest that a lithium trial may be indicated in such patients. Firm conclusions and recommendations must await the evaluation of such schizophreniform illnesses and lithium response using double-blind, placebo-controlled methodology to rule out the possibility that spontaneous remission regularly occurs in such patients during weeks 3 and 4 of hospitalization.

"Schizoaffective Disorder": An Invalid Diagnosis? A Comparison of Schizoaffective Disorder, Schizophrenia, and Affective Disorder

BY HARRISON G. POPE, JR., M.D., JOSEPH F. LIPINSKI, M.D., BRUCE M. COHEN, M.D., PH.D., AND DORIS TOBY AXELROD, A.C.S.W.

The authors compared patients meeting widely accepted criteria for the diagnosis of schizoaffective disorder, manic type, with patients meeting rigorous criteria for manic disorder and schizophrenia, using three methods of validation: family history, short-term treatment response, and long-term outcome. No significant differences were found between patients with manic disorder and schizoaffective disorder. However, consistent and often highly significant differences separated patients with schizophrenia from those with manic disorder and schizoaffective disorder. The findings suggest that schizoaffective disorder, as currently defined, *is not a valid and independent entity. The authors suggest that psychotic disorders not diagnosable as manic-depressive illness or schizophrenia and without apparent organic basis would best be called "undiagnosed" or "atypical" psychosis. Further, while proposals for new diagnoses or for subtyping of schizophrenia or manic-depressive illness should be encouraged, these should undergo rigorous screening for validity before being accepted into clinical use.*

The diagnosis and nosology of psychotic disorders have been matters of interest and debate since Kraepelin's original delineation of manic-depressive illness and schizophrenia (1, 2). Although in the past it was largely of academic interest, the nosology of these disorders has now assumed greater importance, as the availability of newer and more specific treatments for the psychoses has required more accurate diagnosis and classification of patients. Furthermore, growing research into the etiology and treatment of the psychoses demands that carefully selected, homogeneous populations of patients be available for study. It is thus crucial to develop a nosology of these disorders in which each diagnostic entity is shown to be valid.

How does one establish the validity of a psychiatric diagnosis? Lacking the histological, pathological, or biochemical evidence used to validate diagnostic entities in most branches of medicine, psychiatry must rely on other validating criteria. These have been reviewed by Robins and Guze (3), who enumerated five criteria for establishing diagnostic validity in psychiatric illness: clinical description, laboratory studies, delimitation from other disorders, follow-up study, and family study. Only by the constant and rigorous testing of the validity of proposed diagnostic entities, using criteria such as these, can we develop a truly useful classification of psychiatric disorders.

Currently, fairly well-validated criteria exist for the diagnosis of schizophrenia and manic-depressive illness, including the criteria of Feighner and associates (4), the Research Diagnostic Criteria (RDC) (5), and the criteria of the 1978 and 1979 drafts of *DSM-III*. However, it is widely recognized that many patients manifest psychotic syndromes difficult to classify under schizophrenia or manic-depressive illness, for example, the patient who manifests an acute psychosis with both "affective" and "schizophrenic" symptoms. Should such patients' illnesses simply be classified as undiagnosed psychosis, should they be subsumed under an already validated diagnosis (i.e., schizophrenia or manic-depressive illness), or can they be shown to represent a valid diagnostic group in their own right?

Many diagnostic terms have been proposed to describe such patients; in the United States one of the most popular has been schizoaffective (6). Schizoaffective disorder has been variously proposed to represent a subtype of schizophrenia (as in *DSM-II*), a subtype of manic-depressive illness (7), or a separate entity (8, 9). The diagnosis of schizoaffective has been in use for nearly 50 years, despite a lack of evidence to establish its validity. Does schizoaffective disorder merit distinction as a valid diagnostic category?

A useful design for testing the validity of the schizoaffective diagnosis is to select three groups of patients: 1) a study group of putative schizoaffective patients who display a defined combination of affective and "schizophrenic" symptoms and two narrowly defined reference groups of 2) "definite" schizophrenic patients and 3) "definite" manic-depressive patients. The study group is then compared with each of the two reference groups on a wide range of available validating criteria such as demographic indices, treatment response, family history, and long-term outcome. A finding of consistent, significant differences between the schizoaffective study group and a given reference group would suggest that the two groups represent different disorders, but a finding of minimal, nonsignificant differences would suggest that the two groups may represent the same disorder.

In a recent study that closely approaches this design, Abrams and Taylor (10) compared 78 patients who met the RDC for manic disorder (5) with 10 patients who also met the RDC for manic disorder but in addition displayed one or more of Schneider's first-rank symptoms (11). This latter group would be defined as having schizoaffective disorder, manic type by both the RDC and in the 1978 draft of *DSM-III*. No significant differences could be found between the manic and schizoaffective patients on any variables related to prognosis, premorbid history, family history, or treatment response. These results would seem to question the validity of the schizoaffective diagnosis and suggest that schizoaffective disorder might be indistinguishable from manic disorder.

A problem with this study noted by the authors is that it included only 10 schizoaffective patients. This causes a risk of a so-called type II error—failure, as a result of small sample size, to demonstrate significant differences between two groups when in fact real differences exist. A second problem is the lack of long-term follow-up: it would be of interest to know whether the two groups were distinguishable in any way several years later.

Three other studies used similar designs to investigate groups of patients who were diagnosed as schizophrenic but who displayed good prognostic criteria such as affective symptoms (12–14), an acute onset of illness (12–14), and/or a past history of a remitting illness (14). A number of these study patients would probably have been diagnosed schizoaffective in many centers. We summarized the results of these three studies in table 5 of a previous report (15). Briefly, all three studies found the good prognosis schizophrenic patients indistinguishable from reference groups of pure bipolar manic-depressive patients on virtually all indices, including demographic data, treatment response, and family history, but significantly different from the reference group of schizophrenic patients on many of the same indices.

However, the first two of these three studies were based on the same series of admissions as was the study of schizoaffective disorder previously described (10). Thus, three of the four studies represent the work of the same group at the same center, which makes the generalizability of the findings less certain.

Several additional studies have used the single validating criterion of family history to compare "schizoaffective" and similarly defined "good prognosis schizophrenic" patients with reference groups of poor prognosis schizophrenic patients. These are summarized in table 3 of our previous review (15). These studies consistently found a preponderance of schizophrenia in the relatives of poor prognosis schizophrenic patients, but a preponderance of affective illness in the relatives of schizoaffective and good prognosis schizophrenic patients, which again suggests that the latter groups represent a disorder separate from poor prognosis schizophrenia.

The present study further tests the validity of the schizoaffective diagnosis, using the widely recognized RDC (5) (which closely resemble the 1978 draft of *DSM-III* criteria) to define patient groups. In order to minimize the possibility of a type II error, we examined a relatively large number of schizoaffective patients. We also conducted a 1½- to 5-year follow-up for most patients. We examined whether the validating criteria of treatment response, family history, and long-term follow-up would significantly distinguish schizoaffective disorder from schizophrenia and/or from affective disorder. Alternatively stated, we asked whether, in patients displaying a full manic or depressive syndrome, the presence or absence of putative schizophrenic symptoms (especially the Schneiderian first-rank symptoms) would have any effect on treatment response, family history, or long-term outcome.

METHOD

We reviewed the charts of 219 consecutively admitted patients to Bowditch I, a research ward for the study of psychotic disorders at McLean Hospital in Belmont, Mass. This group represented all of the patients admitted during the period from January 1, 1974, to July 1, 1977. Charts contained detailed admission notes, mental status examinations, physicians' progress notes, case reports, and daily notes by the trained nursing staff of the research unit. In addition, most of the 219 patients were directly known to one or another of us from our work on the unit. Thus, in spite of our retrospective approach, there were extensive data on each patient.

We diagnosed the patients using the RDC (5) (which closely resemble the criteria of the 1978 draft of *DSM-III*). However, for the reference group of schizophrenic patients we required 6 months of illness, as noted in the *DSM-III* criteria, rather than only 2 weeks as required in the RDC. This was done in order to ensure

TABLE 1
Research Diagnostic Criteria Diagnoses of 219 Consecutively Admitted Patients

Diagnosis	N	%
Schizophrenia	41	18.7
Schizoaffective disorder, manic type	52	23.7
Schizoaffective disorder, depressed type	9	4.1
Manic disorder	34	15.5
Major depressive disorder	4	1.8
Unspecified functional psychosis	12	5.5
Other disorders (psychoses of possible organic etiology, factitious psychoses, psychoses of less than 1 week's duration, and nonpsychotic disorders)	67	30.6

that the reference group of schizophrenic patients would be as strictly defined as possible. The distribution of diagnoses of the 219 patients is shown in table 1.

Three diagnoses—schizophrenia, schizoaffective disorder, manic type, and manic disorder—collectively accounted for 57.9% of the patients. The paucity of depressed patients on the unit was due to the fact that most such patients were routinely sent to two other units. The large number of patients classified in the category of other disorders included many who were disqualified because of a possible organic etiology (such as abuse of hallucinogens or sympathomimetic substances), plus a not inconsiderable number of patients (N=13) who we felt displayed factitious psychotic disorders.

The 127 patients fulfilling RDC for schizophrenia, schizoaffective disorder, manic type, and manic disorder were selected for study. These groups were compared using three validating criteria: 1) family history of schizophrenia, affective disorder, and alcoholism; 2) short-term treatment response; and 3) long-term outcome at 1½ to 5 years after discharge.

Family history was rated by abstracting available information about ill relatives. These data were later scored by one of us (H.G.P.), who was blind to the diagnosis of the proband, using the criteria of Winokur and associates (16) for the diagnosis of family members.

Short-term treatment response was scored directly from the wording used in the physician's discharge summary in order to minimize any bias in our own retrospective assessment of short-term response. Patients were divided into three categories: 1) those rated "worse," "unimproved," or "slightly improved" by their physicians; 2) those rated "moderately improved"; and 3) those rated "markedly improved" or "in remission."

Long-term outcome was rated by one of us (D.T.A.), who was blind to the research diagnosis that had been assigned to the patient. However, blindness to diagnosis in this instance was only partial since the outcome rater had seen many of the patients earlier during their index admissions. Outcome data were obtained by telephone or personal contact with the patient, information from patients' therapists, and review of the records of hospital admissions subsequent to the index admission. Outcome was evaluated for the entire follow-up period since the index admission (i.e., 1½ to 5 years). Four indices were defined and rated:

1. Best social function at any time during the follow-up period.
2. Maximum occupational or academic level at any time during the follow-up period.
3. Lowest level of residual symptoms at any time during the follow-up period (residual symptoms were defined as the eight symptoms listed under part C of the *DSM-III* criteria for schizophrenic disorder).
4. Global assessment of outcome for the period as a whole.

Each of the four indices was rated on a 5-point scale (0=poor, 1=fair, 2=moderately good, 3=very good, 4=excellent).

Thus, by abstracting and blind scoring family histories, using treating physicians' ratings of outcome, and by partially blind scoring of long-term outcome, we attempted to minimize the effects of bias in any of the three validating criteria employed.

RESULTS

Family History

Table 2 indicates the number of patients in each of the three diagnostic groups (schizophrenia, schizoaffective disorder, manic type, and manic disorder) found to have a positive family history for schizophrenia, affective illness, alcoholism, and psychotic disorders for which data were inadequate to permit a diagnosis. In some instances, we felt that the family of a given proband contained a possible rather than a definite case of affective illness or alcoholism; such cases are shown separately in the table.

A positive family history for schizophrenia occurred in 9.8% of schizophrenic probands and none of the schizoaffective and manic probands. Using a one-tailed t test, this significantly differentiated schizophrenia from schizoaffective disorder, manic type ($p=.04$) and showed a similar but nonsignificant trend ($p=.09$) in comparing schizophrenia with manic disorder. The low incidence of familial schizophrenia in our study, even in the families of patients with schizophrenia, is consistent with the findings of a number of other investigations (11–14, 17).

A positive family history for affective illness significantly differentiated schizophrenia from schizoaffective disorder, manic type, and from manic disorder. However, there was no significant difference in family history of affective illness between schizoaffective disorder, manic type, and manic disorder. These findings hold true whether or not "possible" cases are included.

In summary, then, the validating criterion of family history suggests that schizoaffective disorder, manic

type, is indistinguishable from manic disorder but significantly different from schizophrenia.

One possible objection that might be raised at this point is that schizoaffective patients are too loosely defined in the RDC; the presence of even one Schneiderian first-rank symptom, or preoccupation with a single delusion or hallucination unrelated to mood, is enough to shift the diagnosis from manic disorder to schizoaffective disorder, manic type. What if one were to examine the more narrowly defined subgroup of schizo-

Schizoaffective disorder, manic type, with 2 or more schizophrenic symptoms (N=24)	2	8.3	16	66.7	6	25.0

[a]Poor-fair outcome is defined as a rating of 0–1, good=2–3, and excellent=4 for best social function, best occupational or academic function, and global assessment of outcome. For minimum residual symptoms, poor-fair indicates severe symptoms, good indicates moderate symptoms, and excellent indicates no symptoms.
[b]Schizophrenia versus all other groups, $p<.001$ (chi-square analysis). All other differences were not significant.

affective patients who showed not one but several Schneiderian or mood-incongruent psychotic symptoms? Would this group still prove indistinguishable from patients with manic disorder?

To investigate the possibility, we examined the subgroup of 33 schizoaffective patients who displayed two or more of the Schneiderian or mood-incongruent psychotic symptoms from the list of symptoms considered suggestive of schizophrenia in criterion C of the RDC for schizoaffective disorder, manic type. Eighteen of these patients showed three or more of such symptoms and 6 showed five or more. However, even this more narrowly defined subgroup proved indistinguishable from manic disorder on all family history indices, but significantly distinguishable from schizophrenia on family history of manic-depressive illness ($p<.001$), and showed a nonsignificant trend on family history of schizophrenia ($p=.09$, one-tailed t test).

Short-Term Treatment Response

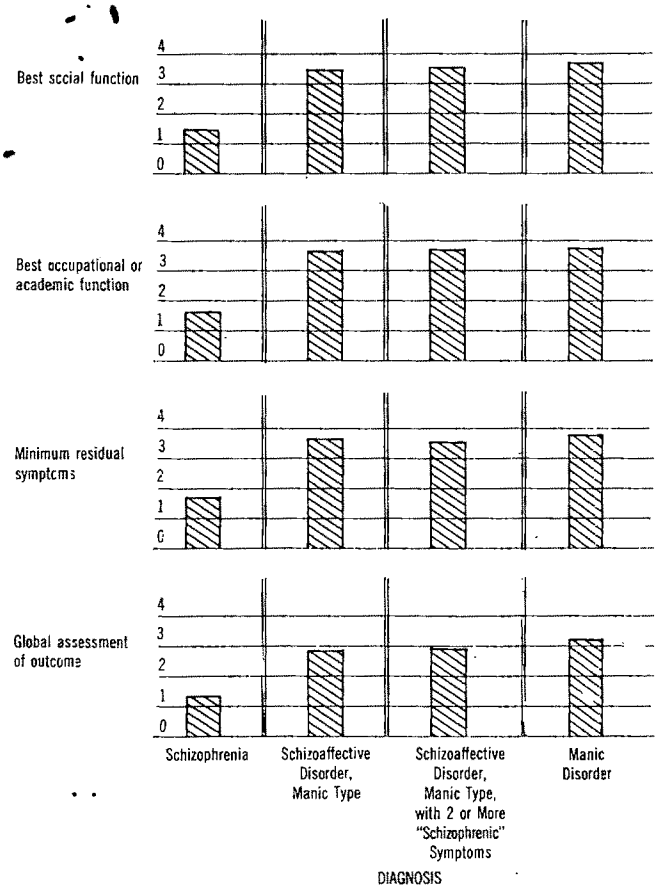

Table 3 presents data on short-term treatment reponse. Medications shown represent those the patient was receiving at the time of discharge. Based on this criterion, a highly significant difference separated the schizoaffective patients from the schizophrenic patients. However, no difference was found between schizoaffective patients and manic patients. Looking again at the subgroup of schizoaffective patients with 2 or more schizophrenic symptoms (i.e., Schneiderian first-rank or mood-incongruent psychotic symptoms) there was a highly significant difference between them and the schizophrenic patients, but not between them and the manic patients. Looking within the various groups at specific medication regimens (for example, lithium alone), there was little difference between the manic, schizoaffective, and schizoaffective patients with 2 or more schizophrenic symptoms.

Thus these findings, like the family history findings, support the similarity of schizoaffective disorder, manic type, and manic disorder, but they suggest the heterogeneity of schizoaffective disorder and schizophrenia.

Long-Term Outcome

Data on long-term outcome are shown in table 4 and figure 1. It is important to reiterate that the indices of social function, occupational or academic function, and residual symptoms rate best functioning at any time during the follow-up interval of 1½ to 5 years. Thus, an individual with several episodes of severe illness, separated by complete remissions, would tend to score high on these indices; an individual with chronic mild symptoms would score lower. On the other hand, global assessment of outcome represents an overall assessment of the entire follow-up period; an individual with several episodes of severe illness would thus

FIGURE. 1
Mean Ratings on Four Outcome Indices of 127 Patients Diagnosed as Having Schizophrenia, Schizoaffective Disorder, Manic Type, and Manic Disorder[a]

[a]0=poor, 1=fair, 2=moderately good, 3=very good, 4=excellent. Mean rating values are available from Dr. Lipinski on request.

score lower, however complete his or her remissions between episodes, than an individual with only a single major episode.

Of the 41 patients with schizophrenia, adequate information was obtained to rate long-term outcome in 27 of them (66%). Eighteen of the patients with manic disorder (53%), 35 of the patients with schizoaffective disorder (67%), and 24 of the patients with schizoaffective disorder with two or more schizophrenic symptoms (73%) could be rated for outcome. There was no significant difference between the proportions of patients in each group for whom adequate outcome data were obtained.

On all four outcome indices, the schizophrenic patients displayed strikingly and significantly poorer outcome than any of the other groups. However, no significant difference was found on any index between schizoaffective patients and manic patients. Nor did any significant differences emerge between the manic patients and the schizoaffective patients with two or more schizophrenic symptoms.

DISCUSSION

In order to test the validity of the diagnosis of schizoaffective disorder, manic type, patients meeting widely published criteria for this disorder (reference 5 and 1978 draft of *DSM-III*) were compared to patients meeting rigorous criteria (reference 5 and 1978 draft of *DSM-III*) for manic disorder and schizophrenia, using three validating methods: family history, short-term treatment response, and long-term outcome.

On all three validating criteria, no significant differences were found between manic disorder and schizoaffective disorder, manic type. No significant differences were found even in comparisons between patients with manic disorder and schizoaffective patients who displayed two or more schizophrenic symptoms (i.e., Schneiderian first-rank symptoms, preoccupation with mood-incongruent delusions or hallucinations, or thought disorder persisting in the absence of affective disturbance). On the other hand, on the same three validating criteria, consistent, often highly significant differences emerged separating patients with schizophrenia from both schizoaffective and manic patients.

Our findings suggest the following.

1. Schizoaffective disorder, manic type (as it is defined by two sets of well-known published criteria [reference 5 and 1978 draft of *DSM-III*]), is readily distinguishable from schizophrenia but indistinguishable from manic disorder using available validating criteria. This suggests that schizoaffective disorder, manic type, is not a valid and independent diagnostic entity but rather should be classified within manic disorder.

2. In patients displaying a full manic syndrome, the presence or absence of Schneiderian first-rank symptoms or of mood-incongruent psychotic symptoms was of no demonstrable diagnostic or prognostic significance in this study. This finding adds to the mounting evidence, from a number of recent studies (15), that Schneiderian first-rank symptoms and other putative schizophrenic symptoms are nonspecific symptoms, occurring frequently in both affective illness and schizophrenia and having little, if any, demonstrated significance in differential diagnosis.

Several limitations in the present study suggest avenues for further investigation. First, the number of depressed patients in our study (4 with major depressive disorder and 9 with schizoaffective disorder, depressed type) is too small to permit conclusions. Our findings for the two groups of depressed patients closely paralleled those for the patients with manic and schizoaffective disorder, manic type, but the numbers were far too small to reach significance. A larger study with depressed patients would be of interest.

Second, the restrospective design of the present study limits the accuracy attainable in some ratings. Some phenomenological or family-history data (especially familial alcoholism) may have been missed in the

retrospective approach. Complete researcher blindness was also impossible to achieve, although partial blindness was attained. To improve on this, we are currently conducting such a prospective study of consecutive admissions in which the admitting diagnosis, family history, short-term treatment response, and long-term outcome are determined by four independent observers, each blind to the ratings of the other three.

Third, the present study examines only one definition of schizoaffective disorder—that of the RDC (5) and the 1978 draft version of *DSM-III*. The final version of *DSM-III* redefines schizoaffective disorder as a residual category, without specific criteria. These narrower, but less specific criteria for schizoaffective disorder are more difficult to test, since it is much harder to get different observers to agree reliably as to which patients merit the newly defined schizoaffective diagnosis. Thus validation of these criteria may prove extremely difficult.

In summary, while the diagnostic separation of schizophrenia from schizoaffective disorder and manic disorder appears to be valid, the diagnostic separation of schizoaffective disorder from manic disorder does not appear to be valid as judged by available criteria. Since course, family history, and treatment response do not distinguish schizoaffective disorder as defined here from manic disorder, there would seem to be no adequate reason on clinical grounds to make the former diagnosis. Such a diagnosis can only lead to confusion.

From this discussion it should not be concluded that schizophrenia or manic-depressive illness necessarily represent unitary, homogeneous diagnostic entities, but rather that no other divisions or diagnostic groupings as yet appear to have proven diagnostic validity. Thus at present it appears that the diagnosis of schizoaffective disorder should be suspended and that individuals without toxic, metabolic, or factitious psychosis who do not fit the above categories would best be given a diagnosis of atypical psychosis or undiagnosed psychosis. Finally, proposals for new diagnostic groups and subgroups should be encouraged, but should undergo rigorous screening for validity before being accepted into clinical use.

Neuropsychology in Alcoholic Men in Their Late Thirties: One-Year Follow-Up

BY KENNETH M. ADAMS, PH.D., IGOR GRANT, M.D., AND ROBERT REED, M.S.

In a previous article the authors reported on two groups of alcoholic men in their late 30s who were remarkably free of neuropsychological impairment. In this article they present the results of a 1-year follow-up of many of these subjects. They found similarities in performance between alcoholic subjects who in the original study had been abstinent for 18 months and nonalcoholic control subjects who drank moderately. However, the group of alcoholic men who in the original study had been recently detoxified (about 3 weeks) failed to show practice-effect learning on follow-up. The authors interpret this failure as possibly indicative of a preclinical phase of what might ultimately become organic impairment.

In 1979 we reported on two groups of alcoholic men in their late 30s who were remarkably free of neuropsychological impairment (1). Furthermore, we found that we could not distinguish between alcoholic men who had been recently detoxified (3 weeks) and those who had been abstinent for 18 months and a control group of subjects who drank moderately on the basis of an extended Halstead-Reitan Neuropsychological Battery (2). We found no evidence from life history, neurological history, drug history, nutritional history, or drinking history (3) which suggested that our subjects were either at special risk for or would enjoy special immunity from alcohol-induced cerebral impairment. In this article we will present the results of a 1-year follow-up of these groups.

METHOD

A comprehensive description of the study design can be found in the initial report (1). In brief, we performed extended Halstead-Reitan neuropsychological examinations on three groups of men at the beginning of the study. Group 1 consisted of inpatients from a Veterans Administration alcoholism treatment unit who had been in the program for 3 weeks. Group 2 were abstinent alcoholic men who had remained sober for 18 months. Group 3 was composed of nonpatients who were recruited from various civic and educational organizations and screened against criteria that would eliminate subjects with "neuropsychological risk" conditions (3). Any subject with a history of neurological disorder, psychosis, or polydrug abuse was excluded, as were subjects older than age 46.

Approximately 1 year after the initial examination we repeated the neuropsychological tests and gathered interim data on health, accident, nutritional, alcohol, and drug abuse histories. There were 23 men in the follow-up group 1 (we will maintain the original group labels even though the "recently detoxified" men had been detoxified for 1 year and 3 weeks at follow-up). The mean age of the men in group 1 was 36.8±6.5 and the mean number of years of education was 12.9±2.0. Group 2 (who had originally been abstinent for 18 months) consisted of 25 men whose mean age was 36.5±6.3 and who had a mean of 13.2±2.7 years of education. In group 3 were 21 nonalcoholic men aged 36.9±5.9 with 13.3±1.7 years of education.

At the time they entered the study, we estimated the amount of ethanol consumed by all of the subjects in the preceding 10 years. The mean values were as follows: group 1, 695 kg, group 2, 675 kg, and group 3, 44 kg ($F=19.0$; $df=2, 66$; $p<.0001$). The number of years of very heavy drinking (defined as years in which ethanol consumption exceeded 560 g per week on the average) was 6.7 years for group 1, 6.5 years for group 2, and 0.2 years for group 3 ($F=35.4$; $df=2, 66$; $p<.0001$). The two alcoholic groups also used more marijuana (approximately three "joints" per week versus essen-

tially none) and more cigarettes (10 versus 3 packs per week) than the nonalcoholic men. None of the subjects reported much experience with other drugs. Detailed comparisons did not reveal any significant differences between the follow-up groups and the original samples (demographic, medical, or substance use histories, nutrition, and initial neuropsychological test results).

The neuropsychological test protocols were grouped together, and one of us (I.G.), who was blind to group membership, rated the performance data on a 6-point scale ranging from excellent to severely impaired (1, 3).

RESULTS

At follow-up 9 men from group 1 (39%), 3 from group 2 (12%), and 3 from group 3 (14%) had mild to moderate neuropsychological deficits ($\chi^2=6.17$; $df=2$; $p<.05$). At the first examination 1 year before, 6 men in group 1 (26%), 5 men in group 2 (20%), and 4 men in group 3 (19%) showed such impairment (the difference was not significant). Initial and follow-up scores for selected neuropsychological tests are presented in table 1.

The alcoholic men who had been abstinent for at

least 18 months and the nonalcoholic subjects improved significantly on several tests and summary indexes including the Category Test, Tactual Performance Test total time, and some Wechsler Adult Intelligence Scale (WAIS) performance items. In contrast the recently detoxified group did not improve significantly on any test, although they did increase their overall performance IQ. This suggests that the recently detoxified group did not benefit as much from practice effect as did the other groups.

Sixty-three percent of the recently detoxified alcoholic men reported having had at least one drink in the follow-up periods, as did 20% of the long-term abstinent group and 48% of the nonalcoholic subjects. Most reports of drinking were extremely modest (a few drinks a month), although 1 man from group 1 reported drinking a quart of whiskey a day for a month 2 months before retesting. We related interim drinking (yes versus no) to follow-up neuropsychological results (unimpaired versus impaired). There was no reliable association. Similarly, neuropsychological status at the beginning of the study did not predict subsequent drinking.

There were no systematic between-group differences in nutritional status (ratings were made by a dietitian) during the follow-up period. Several group 1 subjects reported interim medical events: 1 man suffered a stroke (although he was rated as much more impaired neuropsychologically at follow-up, he was also mildly impaired before the stroke), another was given diphenylhydantoin because of a seizure, and a third suffered a concussion in an auto accident. The latter 2 subjects remained unimpaired at follow-up. No important medical events occurred in groups 2 or 3. Thus, the increased proportion of neuropsychological impairment in group 1 at follow-up cannot be explained on the basis of available interim drinking, drug use, or dietary or medical history.

COMMENT

Our initial results (1) suggested that there were no systematic neuropsychological differences between two groups of abstinent alcoholic men (those recently detoxified and those who had been abstinent for 18 months) and a nonpatient matched sample of men without a heavy drinking history.

Repeat neuropsychological assessment of these subjects at 1 year follow-up suggests that subtle changes may have occurred. Taken as a whole, our neuropsychological results show similarities in performance between longer-term abstinent alcoholic men (group 2) and the nonalcoholic control subjects (group 3). The recently detoxified group (group 1) seemed to perform differently from the other groups at follow-up.

The clinician's global ratings showed a trend toward improvement in the alcoholic men who had been abstinent for a longer time (group 2) and the nonalcoholic subjects (group 3); this trend was also reflected in improved scores on about one-fourth of the neuropsychological tests. This may reflect actual improvement in cerebral functioning, along with whatever small amount of variance is attributable to practice effects.

In contrast, the recently detoxified alcoholic men (group 1) not only failed to produce improved performance on retest, but in some cases they were actually more impaired according to the clinician's global rating.

These findings might plausibly be interpreted to mean that at initial examination the recently detoxified alcoholic men, although able to perform tests at an essentially normal level, nevertheless had difficulties in the kind of incidental learning that helped subjects in the other two groups do better when retested. Such a defect in incidental memory might reflect a persisting subclinical "intermediate duration organic mental disorder," evidence for which has been presented by Bennett and associates (4) in alcoholic subjects and by us (3, 5, 6) among polydrug users.

Some of our results are comparable to the results of Long and McLachlan (7), who studied a smaller sample of alcoholic men who had been abstinent for a year at follow-up. Their subjects were 8 years older, on the average, than our subjects and more intelligent as measured by the WAIS.

Direct comparison of the changes in Long and McLachlan's subjects and ours shows that five of the seven indicators that showed significant improvement in their study were also significantly improved in our abstinent alcoholic group. Among our nonpatient control subjects, four of the seven tests showed greater than chance improvement, but our recently detoxified alcoholic men had no test improvement comparable to Long and McLachlan's abstinent group.

Some procedural differences make direct interpretation of this comparison difficult. Long and McLachlan obtained differences between their older alcoholic subjects and volunteer control subjects at initial testing, but they did not retest their control subjects. Further, the period between detoxification and testing in their initial examination of the alcoholic subjects was about half that of our study (11 versus 21 days).

The fact that several of our recently detoxified subjects actually deteriorated over a year is puzzling. We found no relationship between medical history, nutrition, drug, or alcohol use in the interim period that would explain the neuropsychological differences among the three groups. There are no readily apparent subject selection factors (health and educational histories were comparable), and the retested samples did not differ from the three initial groups on any relevant dimension. It is, of course, possible that the recently detoxified alcoholic subjects drank more in the follow-up period that they admitted and that such interim in-

toxication contributed to a deficit. Although we cannot dismiss such an explanation, we believe its credibility is weakened by the fact that the alcoholic subjects who reported drinking very heavily since the initial assessment showed no neuropsychological deterioration at follow-up.

Deserving of further exploration is the possibility that some men in the recently detoxified group have entered a process of change in their neuropsychological abilities that is no longer correctable by abstinence.

We suggest that alcoholism-related organic mental disorder might have a latent phase similar to that described for many chronic medical illnesses such as diabetes. According to this model, people destined to develop neuropsychological impairments (either purely on the basis of alcoholism or because of some interaction among constitutional factors, drinking, and normal aging) must at some point in the evolution of their disorder experience early subtle changes in cerebral functioning that are not yet measurable even by extensive neuropsychological testing. A clue to this latent phase might be failure of incidental learning as reflected by lack of expected improvement in test performance at follow-up. With the passage of time, the process might advance to a subclinical phase. At this point a person would still appear "normal" in the usual clinical sense but show signs of neuropsychological deficit on comprehensive examination. Most neuropsychological studies of alcoholics reported in the literature thus far appear to have studied subjects with such a subclinical disorder (8–14). Eventually, some people would be expected to enter a clinical phase characterized by definite signs of cognitive decline, the final outcome of which is classical Wernicke-Korsakoff dementia (15).

Clearly, a report on a small number of subjects followed for a year can offer only tentative support for the model of the natural history of alcoholism-related cerebral disorder that we have proposed. The real test will come when we and others have examined larger and more diverse groups of alcoholic subjects over much longer time spans. Such investigations are time-consuming and costly. At the same time, we probably have reached a limit to the amount of new information that cross-sectional studies, no matter how elegant, can provide about the long-term effects of alcoholism on CNS function.

Neuropsychological Deficits in Alcoholic Men in Their Mid Thirties

BY MICHAEL J. ECKARDT, PH.D., RALPH S. RYBACK, M.D., AND CHARLES P. PAUTLER, PH.D.

The authors examined performances on 24 commonly used clinical neuropsychological tests for drug-free alcoholic men in their mid to late 30s either within 2–6 days of their last drink (N=59) or between 14 and 31 days after their last drink (N=20). Although mean scores were indicative of impairment on approximately half of the tests, no statistically significant overall difference in performance between individuals tested at these two time periods was observed. Recent and chronic alcohol consumption variables were found to interact with each other and with age and education in a nonlinear fashion in predicting neuropsychological performance. Increased consumption predicted decreased performance even on tests whose mean scores were in the normal range.

Although sober alcoholics do not possess overall intellectual impairment (1, 2), they have deficits in perceptual capacities, conceptual shifting, motor performance, memory function, and visual-spatial abstracting abilities (1, 3–6) and consequently have been compared to people with organic brain damage (7–11). These results become even more convincing when it is noted that many of the neuropsychological tests commonly used to assess alcoholism-associated brain dysfunction have been demonstrated to be valid (12, 13) and clinically reliable (14, 15). Reduced cognition in alcoholic patients has been related to length of alcoholism (9, 16, 17) and to pattern of alcoholic drinking even when mean test scores are in the normal range (6). Fine and Steer (18) reported brain damage coincident with early alcohol dependency, and Parker and Noble (19) demonstrated that the amount of alcohol consumption per drinking occasion was negatively related to performance by social drinkers on several cognitive tests. These findings are strikingly different from those of the study by Grant and associates (20), who opted for "cautious optimism that even very heavy alcohol use (80 g/day, or more) is not related to neuropsychological impairment in the alcoholic who is in his or her late 30s."

This conclusion by Grant and associates (20) has serious clinical implications, particularly in view of the enormity of alcoholism as a social problem. Specifically, if clinicians believe that no harm will result from drinking heavily to individuals who are less than 37 years of age, efforts to intervene in this large population might not be highly motivated. Thus, additional studies of this age group should be conducted so that the generality of the findings of Grant and associates (20) to other clinical populations can be assessed. We undertook this prospective study to determine whether recent and chronic alcohol consumption variables were related to neuropsychological performance in alcoholic men in their mid 30s.

METHOD

The subjects were 79 male volunteers who were between the ages of 21 and 46 years and were inpatients in the Alcohol Treatment Program of the Veterans Administration Hospital, Long Beach, Calif. These patients were an age-selected subsample of those alcoholic men between the ages of 21 and 60 years previously reported on by Eckardt and associates (6, 21). They were admitted with a primary medical diagnosis of alcoholism and had no other psychiatric disorder. Informed consent was obtained after the procedure had been fully explained. We used a table of random numbers to assign patients to one of two groups. Group 1 (N=59) was tested within 2–6 days of their last drink, and group 2 (N=20) was tested between 14 and 31 days after their last drink. Group designation was independent of the intensity of withdrawal. Group 1 contained more patients than group 2 because the

latter was originally viewed as a control group for repeated-testing effects (21). The patients in group 1 had a mean age of 36.1±7.2 years, and those in group 2 were aged 34.4±7.9 years.

Neuropsychological testing was conducted by study personnel specifically trained and familiar with the tests used. Testing was conducted after the clinical symptoms associated with acute withdrawal (extreme tremulousness, ataxia, and diaphoresis) subsided. Patients were tested individually after it was determined that no psychoactive medication had been administered during the previous 48 hours. The battery of 24 neuropsychological tests was given over a 2-day period; the order of tests was determined randomly. Tests were selected on the basis of common clinical use and recent literature reviews on brain dysfunction in alcoholics and have been described elsewhere (6, 21).

Detailed information on recent and chronic alcohol consumption, drinking-related behavior, physical and mental health conditions that might influence neuropsychological performance, use of drugs, and socioeconomic characteristics was obtained from research questionnaires filled out by the patient approximately midway through the 21-day treatment program. Occasional discrepancies between this information and medical charts were resolved through an interview by study personnel, who were not members of the treatment staff.

RESULTS

Comparison of Group 1 and Group 2

There were no significant differences between the two alcoholic groups in age, education, marital status, race, personal monthly income, current employment status, recent and chronic alcohol consumption, or drinking-related behavior. One of the subjects in group 1 (2%) and none of the subjects in group 2 had completed grade school only, 28 in group 1 (47%) and 7 in group 2 (35%) had completed high school, and 30 in group 1 (51%) and 13 in group 2 (65%) had completed college. Thirty of the subjects in group 1 (51%) and 10 in group 2 (50%) were married, 17 in group 1 (29%) and 6 in group 2 (30%) were widowed or divorced, and 12 in group 1 (20%) and 4 in group 2 (20%) were single. Twenty-four subjects in group 1 (41%) and 12 in group 2 (60%) had an income of $100–$499, 16 in group 1 (27%) and 6 in group 2 (30%) had an income of $500–$899, and 19 in group 1 (32%) and 2 in group 2 (10%) had an income of $900 or more. The mean number of years of abusive drinking in group 1 was 12.0±7.6, and the mean for group 2 was 13.4±8.2. The mean lifetime consumption of 100% ethanol was 483±450 gallons in group 1 and 548±501 gallons in group 2. The mean number of grams of ethanol per kilogram of body weight per drinking occasion during the past 6 months was 2.4±0.7 in group 1 and 2.8±0.9 in group 2. The mean number of drinking occasions during the past 6 months was 337±200 in group 1 and 352±225 in group 2. Thirteen subjects in group 1 (22%) and 7 in group 2 (35%) had a history of delirium tremens, 7 in group 1 (12%) and none in group 2 had a history of seizures, 55 in group 1 (93%) and 16 in group 2 (80%) had a history of blackouts, and 25 in group 1 (42%) and 7 in group 2 (35%) had received treatment for alcoholism before.

[a]Performance at a level associated with brain dysfunction according to descriptive references in Eckardt and associates (6, 21).

The subjects' performance on the 24 neuropsychological tests are summarized in table 1. It is apparent that mean scores were at levels indicative of brain dysfunction on 13 of 24 tests for group 1, tested within 2 and 6 days of their last drink, and 11 of 24 tests for group 2, tested between 14 and 31 days after their last drink (see table 1). These results are similar to those reported by other investigators (1, 3, 5) and differ markedly from those of Grant and associates (20).

Multivariate analysis of variance procedures demonstrated that performance over all 24 tests did not differ as a result of past or present medical ailment. These ailments were dizziness, severe head injury, headaches, anxiety, depression, nervousness, excessive sleepiness, unconsciousness, difficulty in concen-

tration, memory loss, abnormal blood pressure, blackouts, delirium tremens, seizures, shakes, or difficulty in sleeping. In addition, neither the use of medication nor illicit drug use over the 6 months preceding treatment was related to neuropsychological performance. Of the patients who used illicit drugs, 2 (2.5%) used glue, 4 (5.1%) used heroin, 6 (7.6%) used LSD, 6 (7.6%) used cocaine, and 26 (32.9%) used marijuana; the average frequency of use of these compounds among users was never more than 1–2 times per month.

Multivariate analysis of covariance, with age and education as covariates, revealed no significant differences between the two groups compared over all 24 tests; i.e., there was no demonstrable improvement in neuropsychological performance between means (±SD) after 5.0±1.3 and 20.8±4.0 days of abstinence. Similar findings in patients between 21 and 60 years of age have already been reported (21). Even though the two groups did not differ significantly in cognitive performance, they were analyzed separately to include a group that approximated the time of testing used by Grant and associates (20).

Analyses for Group 1 (N=59)

We have reported that polynomial regression models involving recent and chronic drinking variables, age, and education significantly predicted neuropsychological performance in alcoholic men (6). Therefore, we conducted a similar analysis using age, education, and four alcohol-consumption variables—current dose (grams of ethanol per kilogram of body weight per drinking occasion), how often the maximum number of drinks was consumed, lifetime gallons of 100% ethanol, and years of abusive drinking at current or greater levels. The analysis consisted of first expanding these variables into a full polynomial equation of degree two. This quadratic equation had the usual linear terms[1] employed by Grant and associates (20) plus the square of each linear term and all combinations of the linear terms in order to represent more complex relationships. This quadratic equation was then inserted into the BMDP9R all-possible subsets regression program, which finds the "best" regression equation for prediction. "Best" is defined in terms of minimizing the standardized total mean squared error of estimation (22). All combinations of independent terms, linear and nonlinear,[2] were considered in the selection of the best equation. We used actual test scores of the 59 alcoholic men tested within 7 days of their last drink as dependent variables rather than using overall clinical ratings as Grant and associates (20) did. We did this to satisfy mathematical concepts inherent to the statistical model and the customary hypothesis testing that is performed.

Of the 24 tests, 21 were significantly predicted by this procedure ($p \leq .05$) with an average R^2 (i.e., the amount of variability or variance explained by the independent variables) of .38, including 8 tests for which the mean score was in the normal range. The only tests not significantly explained were Tactual Performance Test-Memory, Block Design, and left-tilt Rod and Frame. Determination of the amount by which R^2 was reduced if drinking variables were removed from the equations revealed that alcohol consumption was involved in 70% of the explained variance, age contributed 20%, and education contributed 10%. Approximately half of the variance related to alcohol consumption was associated with chronic variables and half with recent variables. The resulting equations were similar to those reported by Eckardt and associates (6), which consisted of linear and nonlinear combinations of variables; no equation contained only linear terms.

We conducted additional regression analyses in which we incorporated the quadratic expansion of age and one of the recent or chronic consumption variables at a time to determine the neuropsychological consequences of different drinking patterns. In the 15 tests for which the models predicted significant amounts of variance, increased consumption was predictive of decreased performance for all tests except Tapping, dominant and nondominant hands ($p \leq .05$). The trend of decreased performance with increased consumption was apparent even on the tests for which the mean score was in the normal range: Tactual Performance test, dominant hand; Digit Symbol; Digit Span; Object Assembly; and the Shipley-Hartford, verbal, abstracting, and conceptual quotient.

Analyses for Group 2 (N=20)

Because there were only 20 alcoholic men tested between 14 and 31 days after their last drink, similar polynomial regression analyses that included the quadratic expansion of age, education, and the four consumption variables could not be accomplished; therefore, only analyses for age and one of the recent or chronic consumption variables at a time were conducted. We found that 13 tests had a recent or chronic drinking variable in the resulting best equation; consumption and age each contributed approximately 50% of the explained variance. In the 11 tests for which a conclusion was possible, increased consumption predicted decreased neuropsychological performance on all tests except right-tilt Rod and Frame and Shipley-Hartford, verbal. The finding of decreased performance with increased consumption held even for tests with mean scores in the normal range, such as Tactual Performance Test, dominant hand; Digit Symbol; and Shipley-Hartford, conceptual quotient. No test score was predicted solely by linear terms.

[1]Of or involving terms of the first degree, such as X_1 and X_2.
[2]Of or involving terms of more than the first degree, such as X_1^2, X_2^2, and $X_1 \times X_2$.

DISCUSSION

Because the reduced level of neuropsychological performance that we observed in this study is similar to levels previously reported (1, 3, 5), our sample is not atypical. We demonstrated that recent and chronic alcohol consumption variables interact with age and education in a nonlinear fashion and that alcohol consumption is involved in explaining significant amounts of variance for commonly used clinical neuropsychological tests. It is clinically not surprising to find that these higher order statistical models were more sensitive than the standard linear models used by Grant and associates (20), when one considers the complexity of the relationships between multiple cognitive functions and recent and chronic drinking history.

Grant and associates (20) reported normal neuropsychological test scores for a group of alcoholic men; we also observed that mean scores for our samples on approximately half of the tests were in the normal range. However, the fact that we demonstrated significant nonlinear relationships between recent and chronic alcohol consumption and normal test scores necessitates discussion of what is implied by the concept of normalcy. It is commonly concluded that when no impairment is found on clinical neuropsychological tests, there is no brain dysfunction. This line of reasoning assumes our clinical assessment instruments are infinitely sensitive and ignores the findings that the brain appears to have a neurological reserve or plasticity (23), which, particularly in younger individuals (24), may allow the brain to reorganize rapidly to a "normal level" of cognitive functioning as measured by clinical neuropsychological tests. Thus, it is difficult to determine the impact of ethanol on brain function at any given point in time because we rarely know what the level of functioning for a particular individual was before heavy and/or chronic alcohol consumption. Accordingly, it is possible to obtain "normal" results for any given person that are actually abnormal in terms of the original (i.e., before heavy alcohol intake) capacity. This concept of "abnormal normals" among alcoholics gains support from our investigation and from the study by Eckardt and associates (6), both of which showed that cognitive performance among alcoholic patients was significantly predicted by nonlinear combinations of recent and chronic consumption variables, even on tests whose mean scores were in the normal range. Additional support derives from the finding of significant negative correlations between normal test scores and current dose of alcohol consumed per drinking occasion by social drinkers (19). In our study, as well as in studies by Eckardt and associates (6) and Parker and Noble (19), increased alcohol consumption was usually associated with decreased cognitive performance.

The observed degree and speed of recovery in pathological states that return to "normal" is obviously related to the time of observation after cessation of the pathogenic insult. If the intensity of insult is small and/or the duration of exposure is short, the period of abnormality may be minimal. Grant and associates (20) gave their patients a clean bill of health on the basis of neuropsychological test scores obtained after 3 weeks of abstinence. Although it is possible that their patients may have been malfunctioning cognitively for the 3 weeks before testing, a recent investigation (21) found no improvement in the cognitive performance of patients tested after 1 week of sobriety and those tested after 2–3 weeks of sobriety other than that resulting from having taken the same set of tests twice; we have confirmed this finding in the present investigation. Nevertheless, the period of cognitive "malfunction" directly related to alcohol abuse, even if it is less than 1 week, is clinically very important. An individual who goes into cardiac failure for even 1 hour because of a known drug reaction is not given a clean bill of health when he or she recovers but is told to avoid the drug and is then monitored clinically. Moreover, if repeated insults that have a neurological impact occur, they might be likely to have a cumulative effect over time. Clinical laboratory tests such as liver function tests become "abnormal" early in excessive chronic alcohol drinking (25); therefore, if such tests were routinely available for brain function, similar early adverse consequences of heavy alcohol consumption could be found. A crucial difference in this analogy is that brain tissue does not have the regenerative capacity of the liver either before or after a person reaches the mid 30s.

Intensity, chronicity, and receptivity to any pathological process are generally acknowledged to be important determinants of outcome. Although both our samples and the one reported on by Grant and associates (20) were from Veterans Administration hospitals and of similar ages (i.e., receptivity), our patients drank significantly more alcohol (i.e., intensity) and had more years of abusive drinking (i.e., chronicity). In fact, the patients in Grant and associates' study (20) ingested relatively little alcohol for a short period of time. Our patients had a significant incidence of delirium tremens, seizures, blackouts, and previous treatment for alcoholism; on the other hand, Grant and associates did not mention these characteristics in their sample. We conclude that the patients in Grant and associates' study (20) had not been drinking sufficient amounts (i.e., intensity and chronicity) to allow the researchers to observe significant dose-effect relationships for neuropsychological testing with the age (i.e., receptivity) of their sample and the statistical procedures used. In contrast, our investigation demonstrated significant nonlinear relationships between recent and chronic alcohol consumption and neuropsychological performance which indicated that increased consumption was associated with decreased cognition.

Accordingly, instead of "grounds for cautious optimism that even very heavy alcohol use is not related to neuropsychological impairment in men in their late 30s" (20), we conclude that alcohol abuse in this age group is associated with clinically detectable cognitive impairment.

ADDENDUM

In this issue of the *Journal,* Adams and associates (26) conclude that their failure to show improved neuropsychological performance in alcoholic men in their late 30s when tested 3 weeks after their last drink and again 1 year later indicates "a preclinical phase of what would ultimately be seen as a more clear organic impairment." In that 63% of their alcoholic patients reported posttreatment alcohol consumption, a recent report by Eckardt and associates (27) would support another interpretation, namely, that verified posttreatment alcohol consumption has adverse neuropsychological consequences and might serve to maintain cognitive performance at original levels.

DSM-III: Psychiatric Diagnosis in a University Population

BY RONNIE S. STANGLER, M.D., AND ADOLPH M. PRINTZ, PH.D.

Using DSM-III *the authors reviewed psychiatric diagnoses in a sample of 500 students at a university psychiatric clinic. They present prevalence data and associated age and sex characteristics of this population in relationship to their diagnostic findings and discuss these in the context of earlier epidemiologic studies and their impact on university mental health services.*

The third edition of the American Psychiatric Association's *Diagnostic and Statistical Manual of Mental Disorders* holds promise for increasingly discrete, uniform, and reliable identification of clinical entities. With this new diagnostic language, clinicians have the capacity to more accurately assess the prevalence of psychiatric disorder; such data are essential to treatment planning, program development, and psychotherapeutic and psychopharmacologic outcome research.

Although epidemiological studies have previously focused on university populations (1–9), the emergence of *DSM-III* warrants fresh examination of this patient group. We present data that identify diagnostic prevalence and associated age and sex characteristics for a sample of students who used a psychiatric clinic. Our findings offer additional empirical information about new diagnostic categories first presented in *DSM-III;* we highlight those data which are consistent with or contradict the suggested descriptors of both old and new categories presented in the field trial manuals.

METHOD

The University of Washington Psychiatric Clinic for Students is an outpatient service housed in a comprehensive outpatient medical facility, Hall Health Center, serving a university population of 37,000 students. All undergraduate, graduate, and professional school students are eligible for the clinic's services. We provide crisis intervention and time-limited psychotherapy to approximately 1,200 students per year. The clinic staff is composed of psychiatrists, a clinical psychologist, psychiatric social workers, and trainees in all these disciplines in conjunction with the training program of the university's Department of Psychiatry and Behavioral Sciences.

During the study, our staff recorded age, sex, ethnic status, and the multiaxial *DSM-III* diagnosis (Axis I, clinical syndromes, Axis II, personality and specific developmental disorders, Axis III, physical disorders, Axis IV, severity of psychosocial stressors, and Axis V, highest level of adaptive functioning) for all patients. We initiated data collection on 500 consecutive patients during our participation in an NIMH-sponsored field trial of *DSM-III*. Although our diagnostic protocol overlapped with a number of *DSM-III* draft revisions, all diagnoses reported in this study have been corrected to agree with the final *DSM-III* terminology.

RESULTS

Of the 500 students evaluated, 63.6% were women and 36.4% were men. The mean age of the students was 25.4 years (SD=5.71, range=17–53); the modal age was 21 years. The ethnic-racial composition of the group (according to a classification recommended by NIMH) was 88.2% white, 5.6% Asian, 3.6% black, 2.4% Hispanic, and 0.2% American Indian.

The diagnostic sample yielded a total of 726 entries on Axes I and II: 548 on Axis I and 178 on Axis II. The majority of patients (63.4%) received only one diagnosis (regardless of axis), 29.2% received two, 6.4% three, and the remainder received four or more.

On Axis I, 75.4% of the sample received only one diagnosis of a clinical syndrome, 8.8% received none, and the balance had three or more such diagnoses. On Axis II, 65.8% of the sample received no diagnosis of a personality or developmental disorder, 32.8% received one diagnosis, and 1.4% received two diagnoses. Axis III was not tabulated for this study and will not be discussed further.

After conclusion of formal participation in the

[a]Diagnoses were included only if there were 10 or more subjects in that subsample.
[b]The difference between men and women was significant ($p<.05$, corrected chi-square).
[c]The level of severity for this diagnosis was collapsed for a uniform data count.
[d]The difference in mean age between the subsample and the balance of the total sample was significant ($p<.05$, t test).

NIMH field trial, several staff members independently began to omit Axes IV and V from their multiaxial diagnoses. These omissions were predominantly in response to a subjective sense of minimal variability in the ratings on these axes. As a result, only 397 of our 500 patients received ratings on Axes IV and V. Data on these axes for the patients so diagnosed revealed that ratings for both scales clustered about the scale

TABLE 3
Sex and Age Characteristics of Most Frequent Axis II Diagnoses for 500 University Students[a]

Diagnosis: Personality Disorder	Number of Diagnoses	Percent of Total Patient Sample (N=500)	Women		Men		Age (years)	
			N	%	N	%	Mean	SD
Borderline	29	5.8	21	72.4	8	27.6	26.5	5.9
Atypical, mixed, or other	28	5.6	19	67.9	9	32.1	24.5	6.1

[a]Diagnoses were included only if there were 10 or more subjects in that subsample.
[b]The difference between men and women was significant ($p<.05$, corrected chi-square).

midpoints. On Axis IV (severity of psychosocial stressors), 61.2% of this subsample was rated as 3 (mild) or 4 (moderate). On Axis V (highest level of adaptive functioning), 62.5% were rated as 3 (good) or 4 (fair). We do not further detail Axes IV and V in our statistical reporting. Assessment of the clinical utility of these scales necessitates correlation with external criteria not included in this diagnostic study (e.g., outcome).

Axis I diagnostic classes with at least 10 diagnoses each are rank-ordered in table 1. Within each of these classes, the two diagnoses with the highest frequency and what percentage they represent of their respective classes are also presented in the table. For all classes except anxiety disorders, the two most frequent diagnoses account for at least 60% of each class's diagnostic total.

Diagnostic classes with fewer than 10 diagnoses each are represented as follows: substance use disorders, 9 diagnoses; schizophrenic disorders, 8; somatoform disorders, 7; other psychosexual disorders, 7; atypical affective disorders, 5; dissociative disorders, 5; psychotic disorders not elsewhere classified, 3; paranoid disorders, 3; gender identity disorders, 2; disorders of impulse control, 1; paraphilias, 1; substance-induced organic mental disorder, 1; other disorders with physical manifestations, 1; and stereotyped movement disorders, 1.

The most prevalent Axis I diagnoses (those with at least 10 cases) are shown in table 2 with their respective sex and age distributions. We tested male-female differences using a corrected chi-square ($p=.05$). The mean age for any given diagnosis was tested against the mean age for the balance of the total sample with t tests ($p=.05$).

A significant age difference was found for only one diagnosis, bulimia: the patients with this diagnosis were younger ($p=.002$). Significant sex differences were found for bulimia ($p=.032$), identity disorder ($p=.032$), and dysthymic disorder ($p=.035$); there were more women than men with all of these diagnoses.

Table 3 extends the same tabulation and statistical procedures to Axis II diagnoses, which, for our sample, included only personality disorders. We found no significant age differences here, but two clear sex differences emerged: histrionic personality disorder was exclusively diagnosed in women ($p=.002$), and compulsive personality disorder was significantly more common in men ($p=.02$).

Personality disorders with fewer than 10 diagnoses per category included passive-aggressive, with 8 diagnoses; narcissistic, with 8; paranoid, with 7; antisocial, with 4; and schizoid, with 1.

DISCUSSION

It is clear from these diagnostic findings that depressive symptoms, irrespective of severity, presence of clear precipitants, pattern of recurrence, or chronicity, account for the majority of this population's diagnostic variance. This global statement is essentially consistent with the findings of earlier university mental health studies (9, 10), but we used *DSM-III*'s greater differentiation of depressive syndromes to provide a more qualitatively and quantitatively accurate picture.

The high frequency of adjustment disorder with depressed mood is to be expected in this population as sequelae to the many stressors of the university experience: relationship conflicts and loss, academic demands and failure, and separation from home and family. Since there is little basis in the literature for predicting the prevalence of major depressive disorder in the student population (7), we can only report our findings and wait for further data from other colleges and universities.

We found the prominence of dysthymic disorder quite surprising. Given that this diagnosis requires a minimum of two years of depressive symptoms, its high frequency in our age-restricted sample supports a late adolescent-early adult onset model. The singularly high prevalence of this chronic form of depression challenges the resources of university mental health facilities, many of which are mandated to provide only short-term psychotherapeutic interventions.

Consistent with the finding of the *DSM-III* draft, dysthymic disorder was significantly more common among women than men. However, this sex difference

did not hold for any other category of depression. Although the draft also predicted a greater prevalence of major depression among women, our data revealed no such difference for this diagnosis or for the adjustment disorders.

Our finding that women constituted the majority of our clinic sample (64%) is in keeping with previous reports (3, 6, 8), but no university mental health research has addressed the issue of sex differences for clearly delineated individual diagnoses. Two new diagnoses, identity disorder and bulimia, were significantly more common among women. For the personality disorders, only histrionic and compulsive disorders revealed clear sex differences: more women had the former diagnosis and more men had the latter. Although *DSM-III* predicted that women would be more likely to fit the categories of borderline, dependent, and avoidant personality disorders, we noted no significant sex differences in these diagnoses. These initial sex prevalence data will need to be further explored in future studies, particularly in the light of changing sex roles and their consequent emotional correlates.

The emergence of bulimia as a diagnostic entity and its striking frequency in our sample serves as one example of the complicated sociocultural issues surrounding femininity. A 1978 study of one variant of this diagnosis, bulimarexia (11), suggested that issues of "female role definition" are central to this disorder's genesis in adolescent women. We believe that our prevalence finding for bulimia represents a conservative accounting of this syndrome in the university population. In addition to patients given this diagnosis, we noted that other cases of bulimia were revealed during therapy; our data entry system had no provision for the inclusion of new diagnoses after intake. It is interesting to note that bulimia was the only diagnosis in our study with a significant age difference. Although patients with bulimia were younger women, their mean age of 21.4 years falls within the usual undergraduate age spectrum.

Conspicuous by their absence in our results, the schizophrenic disorders accounted for only 1.5% of our diagnoses. Although previous studies have attempted to survey the prevalence of psychotic illness in university populations (4, 6), only rarely has attention been paid to factoring out the affective and paranoid psychoses from schizophrenia. Our low frequency of schizophrenic disorders requires further investigation, but the altered diagnostic criteria of *DSM-III* may partially explain this finding. The newly defined diagnoses of borderline and schizotypal disorders may now include patients previously diagnosed as having variants of schizophrenia (e.g., latent, simple, residual) in the *DSM-II* nomenclature.

The high frequency of psychophysiologic disorders and conditions not attributable to mental disorder (V codes) in our population is striking. As Reifler and associates (3) suggested, we may anticipate encountering a wider spectrum of problems in living in university psychiatric clinics as services become increasingly available. Apart from the issue of treatment availability, additional factors that contribute to the appearance of these diagnoses include increased public and professional acceptance of intervention in such areas, the emergence of short-term, more visible, and clearly defined treatment approaches (e.g., biofeedback training, couples therapy), and an increased focus on preventive strategies in psychiatry.

As university populations become increasingly heterogeneous with respect to age, sex, ethnicity, and socioeconomic status, the range of psychiatric diagnoses available for study extends toward an approximation of the general population and offers a more viable base for clinical inquiry. The cutting edge of *DSM-III* will expose our "unweeded garden" and challenges us to be more precise in our diagnostic formulations, more focused in our treatment planning, and more accountable to our supporting institutions.

Age, Dementia, Dyskinesias, and Lithium Response

BY JONATHAN M. HIMMELHOCH, M.D., JOHN F. NEIL, M.D., SUSAN J. MAY, R.N., DR.P.H., CARILYN Z. FUCHS, PH.D., AND SANDRA M. LICATA, R.N.

Nineteenth-century neuropsychiatrists felt that the aged bipolar patient usually developed chronic mania, which eventually turned into dementia. The authors' elderly patients seemed to experience few such denouements, so they evaluated the course and treatment response of 81 bipolar patients over the age of 55. Fifty-six responded well to lithium. Advanced age had no effect on course or outcome. However, with increased clinical evidence of neurological illness there was an increased incidence of chronic mania, a poorer response to lithium, and more frequent and severe neurotoxicity. Extrapyramidal syndromes were particularly devastating.

King David and King Solomon led merry, merry lives
With many, many concubines and many, many wives.
But when old age came over them with its many, many qualms,
King Solomon wrote the proverbs and King David wrote the psalms.

—*Shul* ditty

The effects of aging on the presentation, course, and outcome of manic-depressive illness have never been thoroughly described. In the 19th century both Kraepelin (1) and Schüle (2) observed that in older patients a chronic manic state could develop out of acute manic excitement. This chronic mania contained not only confusional elements but a certain "psychobiological rigidity" (3) that foreshadowed the almost inevitable development of full-blown dementia. Yet even within the extremely ill populations cared for by late 19th-century alienists, this sequence of events—acute mania, followed by chronic mania, ending in dementia—was not the lot of every elderly manic-depressive patient. Mendel (4), for example, pointed out that most manic psychoses did not end this way and felt that the chronic manic states described by Kraepelin and Schüle were simply dementia with excitement, totally unrelated to true mania.

The past two decades have afforded a better opportunity to increase our rather incomplete understanding of the effects of aging on manic-depressive illness. Increased longevity has produced more elderly patients. The availability of lithium salts has not only provided effective treatment but has led to the creation of lithium clinics, where large numbers of elderly subjects with both early and late onset manic-depressive illness are treated. Moreover, not all of these patients are extremely ill, like those of Kraepelin's time, so that the effects of aging can be studied within a spectrum of severity. It is from such a sample that the effects of aging on the course of illness and the treatment response can best be studied and the true incidences of both chronic mania and neurological deterioration be gleaned.

This paper describes a detailed investigation of 81 patients between the ages of 55 and 88 who were treated with lithium salts at the Affective Disorders Clinic of the University of Pittsburgh.

METHOD

We studied the charts of 81 patients, who represented 81 consecutive admissions (from 1973 through 1976) of patients over age 55 with manic-depressive illness. Diagnoses were made using the Kupfer-Detre system (KDS) (5). All 81 patients met Feighner's criteria (6) for primary bipolar affective disorder. The Schedule for Affective Disorders and Schizophrenia-Research Diagnostic Criteria (SADS-RDC) (7) were not used at the clinic until late 1976, but it is probable that all 81 patients would also fulfill these criteria. Seven of the 81 patients were disabled only during their depressive phase and therefore merit the diagnosis of bipolar II (8). The remaining 74 were diagnosed bipolar I.

Data were collected on the following variables: sex, present age, age of onset of manic-depressive illness, drug or alcohol abuse, dementiform features, extrapyramidal syndromes, neurotoxic reaction to lithium, development of chronic mania, and significant medical

Presented at the 131st annual meeting of the American Psychiatric Association, Atlanta, Ga., May 8-12, 1978. Received July 17, 1979; revised Dec. 27, 1979; accepted Feb. 11, 1980.

From the Department of Psychiatry, University of Pittsburgh School of Medicine (Drs. Himmelhoch and Neil), and the Affective Disorders Clinic, Western Psychiatric Institute and Clinic (Drs. May and Fuchs and Ms. Licata), Pittsburgh, Pa.

illnesses. Lithium response was rated on a six-point scale of clinical efficacy. Ratings were defined as follows:

1. Optimum—remission of symptoms within three weeks of the start of lithium therapy without subsequent relapse.
2. Good—remission of symptoms within three to eight weeks of the start of lithium therapy without relapse.
3. Adequate—remission of symptoms during lithium therapy but subsequent relapse usually associated with poor compliance; manageable on an outpatient basis.
4. Poor—incomplete remission of symptoms during lithium therapy and/or at least one relapse during lithium therapy and requiring hospitalization.
5. Minimal—little symptomatic response to lithium therapy.
6. None—no response or worsening during lithium treatment, frequently the result of neurotoxicity at very low lithium doses and low plasma lithium concentrations.

Habitual drug and alcohol use was defined as in previous investigations (9). A patient was considered to be a habitual drug user if he or she used four or more standard doses of sedatives, minor tranquilizers, or psychomotor stimulants per day, three months or longer, and had had difficulty stopping these medications because of withdrawal symptoms. Alcohol abuse was defined according to criteria in *DSM-II*, i.e., "alcohol intake great enough to damage physical health or personal or social functioning; or to be the prerequisite of normal functioning."

Dementiform features were divided into two types: 1) the presence of confusion and/or disorientation only during an affective episode (episodic confusion), and 2) the presence of mild residual dementiform symptoms on mental status examination or on neuropsychological testing between, as well as during, affective episodes (dementia always present). Dementiform symptoms included poor memory, dysphasia, and/or concrete thinking or perseveration, but no frank disorientation to time, place, or person.

Extrapyramidal dysfunction in this sample included only parkinsonism and/or facial dyskinesia. Parkinsonism was defined as the presence of parkinsonian symptoms on the basis of idiopathic Parkinson's disease or on the basis of atherosclerosis, but not on the basis of ingestion of neuroleptic drugs. Facial dyskinesias were probably all neuroleptic related but had to persist after discontinuation of major tranquilizers in order to be recorded as present.

RESULTS

The most important overall result of this study was that 56 of the 81 elderly bipolar patients responded well (ratings of 1–3) to lithium carbonate. However, it is notable that 23 of the 25 poor responders (ratings of 4–6) had manifest neurological illness. Nineteen patients developed chronic mania. All were poor responders; 17 had hard neurological illness (12 had extrapyramidal syndromes, and 5 chronic dementia).

The relationship of lithium response to other variables is shown in tables 1 and 2. Table 1 shows no significant differences between good and poor responders related to present age, age of onset, duration of manic-depressive illness, or presence of medical illness. Abuse of drugs appeared to significantly interfere with lithium response. There was a significantly greater incidence of poor treatment response among men. However, this finding disappeared in later analyses that controlled for neurological status and drug abuse (see below and table 3), probably because of the known higher incidence of both alcohol abuse and cerebral vascular disease among men.

Table 2 shows the devastating effect of worsening neurological status on response to lithium treatment. Neurologically normal patients and those confused only during affective episodes all had some response to lithium; the great majority of those with episodic confusion had "good" or "adequate" response. No neurologically well patient developed chronic mania. Patients with dementiform features tended to have a poorer lithium response, with 2 patients showing signs of toxicity at low serum lithium levels and 5 patients developing chronic mania. Patients with extrapyramidal syndromes had a profoundly worse response to lithium, with 12 patients developing chronic manic states. Eleven of the 15 patients with extrapyramidal syndromes developed neurotoxicity at low doses and low serum levels of lithium. In all but one case neurotoxicity developed at such low serum lithium levels (0.45–0.65 mEq/liter) that increase of lithium dose during affective relapses was precluded.

We performed stepwise discriminant analyses to determine which characteristics most clearly distinguish good from poor treatment response and which distinguish absence from presence of neurotoxicity. Table 3 summarizes the results of these two analyses and illustrates that only three of the six variables entered into the analyses were used to discriminate fully. Neurological illness constitutes almost the entire weight in determining treatment response, with minor additional weights contributed by drug abuse and medical illness.[1] The discriminant function is extremely powerful, correctly classifying over 95% of the cases and resulting in a canonical correlation of .85. A three-way analysis of variance was performed on treatment response ratings to estimate the significance of the effects of neurological status, drug abuse, and medical

[1]Forty-seven patients had 88 medical illnesses; the predominant illnesses consisted of hypertensive, arteriosclerotic heart disease (43 cases), endocrine disease (12 cases), diabetes (4 cases), and thyroid disease (8 cases).

illness. Main effects of neurological illness ($F=80.63$, $df=4$, $p<.00005$) and drug abuse ($F=12.35$, $df=1$, $p<.001$) were highly significant. There was no significant effect of medical illness, nor were there any significant two- or three-way interactions.

The discriminant function for neurotoxicity was slightly less powerful (see table 3) due to the limited number of patients with neurotoxicity. Nevertheless, the major weight was again contributed by neurological illness. Drug abuse contributed substantial additional weight. There was a minor residual contribution made by age. However, univariate F tests on these three variables were significant only for neurological illness ($p<.0001$) and drug abuse ($p<.05$). Drug habituation and tolerance are, in fact, a type of reversible neuropathology, and in the above analyses they acted like mild neurological illness in their adverse effects on treatment response, their facilitation of lithium-induced neurotoxicity, and their association with chronic mania.

DISCUSSION

Since the end of the 19th century it has gradually become accepted that age has important effects on the clinical manifestations, course, and outcome of manic-depressive illness. Investigations have shown that older bipolar patients not only have a tendency to experience shallower and more frequent cycles (10), but also are more likely to develop unipolar or chronic mania (11). Our data make it clear that neurological status, not age, is the critical factor in determining the natural course of manic-depressive illness in the elderly. Neurological status not only determines the evolution of chronic mania, it also predicts poor treatment response and lithium-induced neurotoxicity. Shopsin and associates (12) observed that patients with an "abnormal baseline neuropathy [may] exhibit a decreased threshold . . . to lithium in that it exposes them to central nervous system toxicity at moderate to low levels of serum lithium," and Hays (13) demonstrated that patients who are older at the onset of bipolar illness have a reduced hereditary predisposition but an increased incidence of EEG abnormalities. The studies of Shopsin and associates and Hays may be integrated with our findings to make the following prediction: the worse the neurological illness, 1) the greater the probability of the development of a chronic manic state, 2) the less the likelihood of a therapeutic response to lithium, and 3) the higher the incidence of neurotoxic complications.

An extrapolation of these trends allows us to define a spectrum that begins with pure primary bipolar affective disorder, moves through a range of bipolar cases complicated by increasingly severe neurological illness, and ends with chronic manic states that are pure neurological illness. This endpoint is probably what Mendel described as "dementia with excitement." Indeed, in the light of this hypothesis, all three 19th-century protagonists—Kraepelin, Mendel, and Schüle—were each accurately describing a different part of this spectrum.

The most theoretically interesting segment of this spectrum is that delineated by the intersection of extrapyramidal syndromes with bipolar illness. It is not too surprising that neurotoxicity and chronic mania would somehow be associated with an overall decrease in neuronal mass, but their predominant relationship to damage of such a specific neuroanatomical structure as the extrapyramidal system suggests that there is an important relationship between the dimly understood biologies of the extrapyramidal system and of manic-depressive illness itself.

What is important for the practitioner is to detect the true culprit, which is not age, manic-depressive illness, or lithium, but neuronal destruction and deterioration. The majority of elderly patients are spared a 19th-century nihilistic denouement by virtue of the fact that they do not suffer from neurological illness. As a result, most elderly manic-depressive patients may be treated in the same ways as younger patients are. Even severe medical illness, providing it does not involve the kidneys or the central nervous system, adds little to predicting outcome. The physician may use the same guidelines for administering lithium salts to the aged as he or she does for any other bipolar patient. For example, the physician should expect the usual adverse effects of drug and alcohol abuse on treatment response. Conversely, the physician can look forward to excellent results from lithium treatment of uncomplicated bipolar illness in elderly patients.

Since the determining factor in lithium treatment of the elderly is neurological status rather than age, the physician should be warned about the necessity of conducting an accurate and comprehensive neurological evaluation of elderly lithium candidates. Any subtle evidence of chronic dementia, particularly of

extrapyramidal movement disorders, should be a warning that lithium treatment must be used very cautiously in order to avoid the possibility of either producing neurotoxicity or of markedly worsening preexisting motor dysfunction. It is primarily in this respect that Van der Velde's warnings (14) that older people require lower lithium doses and respond at lower serum lithium levels is useful. Finally, since some investigators (15–17) have suggested lithium carbonate in the treatment of tardive dyskinesia, our data should serve as a warning that lithium salts must be used with great care in this population of patients.

Validity of the MMPI with Native Americans

BY DAVID POLLACK, M.D., AND JAMES H. SHORE, M.D.

A study was conducted to determine the validity of the MMPI for 142 American Indian patients from Pacific Northwest tribes. All the MMPI profiles were similar and had significant elevations in the Sc, Pd, and Pa scales. There was no significant difference between diagnostic groups on many clinical scales. Nonpsychotic, depressed Indian patients could not be distinguished from schizophrenic patients on any clinical scale, and there were no significant differences between antisocial-alcoholic patients and those with situational reactions. There were minimal differences between the Northwest Coast, Plateau, and Plains cultural groups. The authors believe that the similarity of all subgroup profiles demonstrates a significant cultural influence on the results of the MMPI in this population of American Indians.

The validity of psychological assessment of minority groups has been challenged because of the significant cultural differential in test response. Nonetheless, many patients from minority cultures are evaluated by standard psychological methods when they seek care in the community mental health system. This evaluation often includes traditional psychological testing, which has been standardized on the majority population. In a clinical assessment psychological test results may have a significant influence on the evaluation of the patient's behavior and problems and on the formulation of the treatment plan. In this article we report the results of an investigation on the validity of the Minnesota Multiphasic Personality Inventory (MMPI) with a population of 142 American Indians.

In a widely quoted study of scholastic failure and personality conflict among American Indian students Bryde (1) used the MMPI to evaluate personality characteristics. He studied eighth-grade American Indian students who had fallen behind white students and compared the personality variables of the two groups. Bryde identified 26 significant differences out of 28 personality variables. On each of these measures the total Indian group revealed greater personality disruption and poorer adjustment. Notable among the more meaningful variables were feelings of rejection, depression, anxiety, withdrawal, and alienation. The American Indian students who dropped out of school showed significant personality differences from the Indian students who remained in school. Kline and associates (2) used the MMPI to assess 30 male native American alcoholics in an inpatient treatment program. They concluded that the general elevation of the profiles suggested that the study group as a whole was very seriously disturbed. Of the 30 profiles, 10 had five or more T scores over 70, and 20 had three or more T scores over 70. The F, Pd, and Sc scales were consistently elevated, and the greatest pathology was found in the group with a major elevation on the Sc scale.

Hoffman and Jackson (3) used the Differential Personality Inventory to study 25 North American Indians hospitalized for the treatment of alcoholism. These patients scored significantly higher than a comparison non-Indian group on 7 of 27 clinical scales measuring cynicism, self-depreciation, and somatic complaints. However, there were no significant differences on scales reflecting character disorder. Hoffman and Jackson concluded that separate norms should be developed and that they should have standardized measures of psychopathology for specific ethnic groups. Padilla and Ruiz (4) reviewed the literature on personality test assessment of Mexican-Americans. They found a paucity of research and concluded that problems involving fluency in English obscured the findings. Davis (5) studied the influence of race on MMPI results. He pointed out that when educational level was controlled there were no race differences on any of the 11 MMPI scales. Davis felt that social and economic variables were as significant as racial differences in affecting the interpretation of the MMPI.

METHOD

This study was conducted to determine the validity of standard MMPI psychological assessment for the

FIGURE 1
MMPI Profiles of 53 Native Americans, by Diagnosis

Mental Health Program of the Portland Area Indian Health Service, a branch of the U.S. Public Health Service. This regional mental health program for American Indians was initiated in 1969 with an interdisciplinary mental health team to develop services for 10 American Indian reservation communities in Oregon, Washington, and Idaho. In 1971 the mental health staff began to use a standardized, computer-scored MMPI. From 1971 to 1974, 142 MMPIs were completed by American Indian patients from Pacific Northwest tribes. The tribal groups belonged to one of three distinct cultures: Northwest Coastal, Plateau, and Plains. The psychological test results were used by local mental health staffs.

In 53 of the 142 cases the patients were independently evaluated by one of three senior mental health consultants, who made a psychiatric diagnosis by *DSM-II* criteria. Twenty-one of these 53 patients were imprisoned for antisocial behavior related to alcohol abuse. Seventeen patients were given a diagnosis of situational reaction, 9 of nonpsychotic depression, and 6 of schizophrenia. The three consultants met weekly to discuss the patient evaluation and diagnostic criteria. Many of the 53 patients were evaluated by at least two of the consultants. We calculated the means of K-corrected T scores from the MMPI profiles and compared them by age, sex, diagnosis, and cultural grouping.

RESULTS

The most impressive finding was the similarity among MMPI profiles (see figure 1). The mean profile for all 142 patients shows significant elevations in the

[a]1=scale having highest mean score; 10=scale having lowest mean score.
[b]Score greater than 70.
[c]For the three primary cultures represented (N=116).
[d]Of patients who received a diagnosis (N=53).

F, Pd, and Sc scale scores. The Pd and Sc scales are among the three scales with the highest scores for each subgroup. Table 1 summarizes the profile patterns for the 11 subgroups. A significant amount of pathology is indicated by the high incidence of mean T scores above two standard deviations (mean score of 70) on the Pd, Sc, and Pa scales. The Pd and Sc scales are above 70 in 9 of the 11 subgroups, and the Pa scale is above 70 in 7 subgroups. Younger subjects had significantly higher scores on the F, Pd, Pt, and Sc scales. Women scored significantly higher than men on the Hy, Pd, Pa, and Si scales, and men scored higher on the Mf scale (masculine-feminine identification).

There were no significant differences between the antisocial-alcoholic patients and the patients with situational reactions or between the schizophrenic and nonpsychotic depressive patients. The combined profile of the schizophrenic and nonpsychotic depression patients was compared to the combined situational and antisocial-alcoholic patient subgroups. The schizophrenic-depressed subgroup scored significantly higher on the D, Hy, Pa, Pt, and Sc scales, but the differences between subgroups was only in the degree of pathology, not in the profile pattern.

There were no significant differences between the MMPI scale scores of the patients from the Coastal culture and those of the patients from the Plateau culture. Patients from the Plains culture had significantly higher F (validity) and Hy scores than the other two cultural groups.

DISCUSSION

The similarities of all the subgroup profiles demonstrate that there is a significant cultural influence on the results of the MMPI in this population of American Indians. It appears that cultural influence overrides individual pathology and personality differences in influencing the pattern of the MMPI. This cultural response is demonstrated by the similarity of profiles between younger and older patients and between men and women, and across diagnoses and cultural subgroups. The higher Sc, Pd, and Pa scale scores may reflect a group that has been defined as bizarre or deviant by the dominant culture. In a recent report on MMPI interpretation, Graham (6) stated that in white Americans the "[48 of 84] individuals do not seem to fit into their environments. They are nonconforming and resentful of authority, and they often espouse radical religious or political views." The responses are compatible with those of an individual raised in a nonwhite minority culture. An American from the dominant culture who has taken the MMPI may meet all the designated criteria of a particular diagnosis, both behavioral and clinical, and be diagnosed correctly by this psychometric method. However, the patient from the dominant culture is being compared on a profile that has been developed by MMPI responses of known cases from the same culture. In the current application of the MMPI to American Indian subjects there has been no such cultural standardization.

The higher scores for women on 6 of the 10 clinical scales point to an important sex differential in response to stress where psychiatric symptomatology is measured by the MMPI. The statistically significant higher score for Indian women on the Pd scale is surprising and is further indication that this deviance is sociocultural rather than psychopathic.

The profiles of the schizophrenia and nonpsychotic depression subgroups do not differ significantly on any clinical scale. Because of the small number of patients

in these two diagnostic subgroups, this finding needs confirmation by additional research. However, the data point to the possibility that cultural influences significantly overshadow clinical and pathological differences in the MMPI response. American Indians with nonpsychotic depression appear to describe their symptomatology in a manner identical to that of schizophrenic Indian patients. This interpretation is supported by independent clinical observations that many American Indian patients with a grief reaction experience auditory hallucinations, that is, hear the voice of the deceased person. An inexperienced diagnostician usually will label these nonpsychotic grief symptoms as schizophrenic.

Significant differences were found between the "more impaired" (schizophrenic and nonpsychotic depressive) patient groups and the "less impaired" patient groups (situational reaction and antisocial-alcoholic). However, these differences were ones of degree, not pattern. Also, the profiles of patients with situational reactions were no different from those of the antisocial-alcoholic imprisoned group. The similarity of profiles for schizophrenic and nonpsychotic depressed patients in the American Indian population indicates that there is no valid diagnostic assistance with this test in confirming a major psychosis. Since higher subscale scores are significantly influenced by cultural differences in test response, the clinician must be cautious in using the MMPI as part of the diagnostic evaluation of American Indian patients. The higher test scores and cultural specificity introduce the likelihood of overdiagnosis and misinterpretation of the clinical status.

While the staff in this study did not find language skill to be an overt problem in the subjects' completion of the MMPI, cultural specificity in the comprehension and interpretation of word meanings can be a significant barrier to cross-cultural psychological testing and psychiatric evaluation. Leff (7) demonstrated that patients from different cultures show a differential ability to distinguish between various affective feelings and that these differences can be documented with a structured psychiatric examination that contains many items similar to various MMPI questions. Leff tested his hypothesis by using material derived from the International Pilot Study of Schizophrenia. In that study of psychiatric patients in nine different countries, a standardized interview schedule was used for assessing the mental state. It was translated from English into the five Indo-European languages (Czech, Danish, Hindi, Russian, and Spanish) used by the countries involved and the two non-Indo-European languages (Yoruba and Chinese). Patients who speak Indo-European languages can differentiate anger from depression and anxiety, whereas non-Indo-European language patients have difficulty differentiating all three emotions from each other.

From another perspective, Glott (8) gathered data to evaluate the MMPI by translating it into German, Spanish, and French. He then administered it to bilingual patients, who took the test in English and in one of the other three languages. The results showed that certain scales (pathology, deviance, and peculiarity) were likely to indicate more abnormality in the translations than in English. None of the American Indian subjects in our study took the test in a second language, but they were raised in cultures removed from a non-Indo-European language by only one or two generations. To our knowledge, no one has evaluated the relationship of English language usage and emotional states in American Indian cultures, but it is possible that like the non-Indo-European patients of Leff's report, the American Indian subjects have difficulty discriminating certain emotional states as defined in the MMPI. This difficulty could raise the score and inaccurately emphasize selected profiles.

Adebimpe and associates (9) recently reviewed MMPI diagnoses of black psychiatric patients and concluded that black-white differences in MMPI norms also may lead to significant misclassification of black patients. Their review demonstrated that blacks scored significantly higher on the validity (F), schizophrenia (Sc), and hypomania (Ma) scales, leading to false positive diagnosis in schizophrenia. While American Indian patients show a different pattern of elevated scales, the impact of the MMPI profile on the diagnostic formulation could be much the same.

Brislin and associates (10), in a comprehensive review of cross-cultural research methods, emphasize the need for extensive investigation in this area:

> The cross-cultural possibilities with the MMPI continue to be intriguing, though there are many who blanch at the sight of the instrument. It would be folly and a waste to dismiss all United States and other MMPI data, suggesting that the only reasonable approach with the MMPI would be to develop cultural norms. It would be equally foolish to tread in this jungle of clinical and psychometric data without utmost caution. No previous MMPI translation or cross-validation study across cultures with commendable accuracy can be found in the literature. What is critically needed is a series of cross-cultural cross-validation studies with the MMPI that document empirically the measured similarities and differences of clinical diagnosis and personality assessment as a function of culture.

While our study focuses on cross-cultural validation of the MMPI and identifies errors of interpretation when using the standard instrument without cross-cultural norms, it may be erroneous to conclude that a modified cultural norm will correct the MMPI for American Indian patients. It is not only cultural norms for standard tests that need development but cultural research that identifies culturally appropriate instruments from the outset. Certainly the use of the MMPI in a cross-cultural setting amplifies the risk of a false perception of the patient's psychological state. While clinical judgments may also be erroneous, a di-

agnostic interview can include techniques that may be more reliable. For example, direct diagnosis can be strengthened by the participation of mental health workers experienced with American Indians (professionals, paraprofessionals, and people involved in traditional medicine) in the evaluation process to provide a cultural perspective for the psychiatric diagnostician. If expert cross-cultural consultation is not available, a healthy skepticism about such testing should replace any standard clinical use of the MMPI until additional research demonstrates a valid clinical application.

EDITORIAL

Sex and Heroin

The relationship between sex and heroin has been the subject of much research and more lucubration. As early as 1926, Rado (1) had developed the concept that equated narcotics injection with sexual orgasm; thus drive reduction in the form of relief of sexual tensions was postulated as the mechanism responsible for the appeal of narcotics.

Although there is ample evidence for this hypothesis in the language and folklore of the street, scientific confirmation has been lacking. In the past the lack of chemically pure and legal heroin has been a major obstacle. However, the shift from a religious-legal to a scientific-therapeutic approach to drug abuse now makes it possible for some of us to study the mode of action of heroin, catching it *in flagrante delicto* by replicating the pharmacologic aspect of the street scene in the laboratory. The availability of pure heroin coincides with the development of improved and sophisticated techniques of analysis (radioimmunoassays) for the quantification of pituitary gonadotropins and testosterone.

Mirin, Meyer, Mendelson, and Ellingboe in their article "Opiate Use and Sexual Function" in this issue provide convincing biochemical evidence of the relation between sex and heroin and for the drive reduction hypothesis. These studies show that the intravenous injection of heroin results in an immediate fall of luteinizing hormone (LH). This response was abolished by pretreatment with naltrexone. Chronic administration of heroin leads to a fall in plasma testosterone, which may account for the persistent dysphoria of the chronic addict. The authors have discovered in yet a third experiment that "heroin-induced suppression of LH secretion was first evident 2–4 hours and was greatest 4–6 hours after unblocked heroin injection." The maximal decline in plasma testosterone occurred 6 hours after injection of heroin.

The authors postulate on the basis of correlative animal work that acute heroin administration has a central effect on the release of hypothalamic luteinizing hormone releasing factor (LRF). The regulation of LH via LRF has been localized to ventral and medial areas of the hypothalamus, areas possessing many opiate receptor binding sites and a high concentration of endogenous opiate peptides.

Again, in an effort to synthesize clinical and physiological knowledge, the authors postulate that the intensive pleasurable "rush" which follows intravenous injection of heroin involves massive release of catecholamines at both central and peripheral sites. The authors are unable to document this suspicion. Fortunately, they have left some work for the rest of us.

In thus tying together laboratory and clinical findings, the authors have done the field of addiction a considerable service and lend support to the drive reduction theory of addiction. These results should command the attention not only of all workers in the field of the addictions but of all those interested in the relation of human function to behavior.

BRIEF COMMUNICATIONS

The Use of a Correctional Setting for Follow-Up Care of Psychiatrically Disturbed Adolescents

BY DOROTHY OTNOW LEWIS, M.D., AND SHELLEY S. SHANOK, M.P.H.

The authors studied the first 88 adolescent boys who were placed on the secure unit of a correctional school during an 18-month period and found that 52 (59.1%) of the boys had previously received psychiatric residential treatment or psychiatric hospitalization. The authors hypothesize that many of these boys may have been transferred from a psychiatric setting to a correctional facility during adolescence when long-standing aberrant behaviors became more threatening to staff. At present the number of psychiatric hospital beds is decreasing and the criteria for hospitalization of children are becoming more stringent. The data indicate that correctional facilities are now expected to function as psychiatric treatment centers for disturbed adolescents no longer welcome in therapeutic settings.

The purpose of this paper is to report the transfer of psychiatrically disturbed children from psychotherapeutic settings to correctional settings as they reached adolescence. It documents the previous placements of a sample of seriously delinquent incarcerated adolescent boys. It also documents the fact that the recognition of serious psychopathology in delinquent children was not the idiosyncratic observation of clinicians seeing the children in adolescence, allegedly a turbulent period of development. Rather, it documents the repeated recognition of severe psychopathology by numerous clinicians who saw these children at different stages of their development throughout childhood.

THE LITERATURE

Several studies (1–3) have reported the subsequent serious psychopathology of formerly antisocial and/or delinquent children. Conversely, Silverman (4) has documented evidence of serious childhood psychopathology in the histories of adult prisoners. Other investigators (5–8) have focused on the early delinquent behavior of psychotic adults. To the best of our knowledge, with the exception of Lauretta Bender's paper (9) on pseudopsychopathic schizophrenia, there has been little in the literature regarding the previous psychiatric placements of delinquent children.

CLINICAL OBSERVATIONS

The present study sprang from the clinical observation that many of the children placed on a secure unit of a correctional school in Connecticut during an 18-month period had previously been identified as psychiatrically disturbed and had been in psychiatric residential treatment or had been psychiatrically hospitalized. For example, one youngster, adopted in infancy, had serious school difficulties in early childhood in spite of what was described as a "high average" intelligence. Throughout childhood he received private outpatient psychiatric treatment and was placed in a special supportive remedial school program. When, at adolescence, he got into a high-speed chase with police while driving the family's car, he was psychiatrically hospitalized. He was unhappy at the hospital (where he was given the diagnosis of borderline schizophrenia) and ran away on several occasions. He was eventually

committed to the correctional school, where he stayed through his 16th birthday.

Another boy, who was the child of two psychotic parents, was first placed in a state receiving home at age 10 when he was found by police wandering the streets aimlessly, "involved in dangerous behaviors." His parents were found guilty of neglect, and the boy was subsequently placed in a psychiatric residential treatment facility. There he was described by clinicians as being "unable to differentiate between reality and fantasy." Over the course of several years he had multiple placements and received multiple psychological and psychiatric evaluations. At age 12, he was described by one psychologist as "filled with poorly formed fearful ideas." A psychiatrist described him at age 14 as "a very disturbed youngster emotionally" who was suffering from a "latent schizophrenia." He was eventually sent to a state psychiatric hospital after having set fires both in a residential treatment facility and in his aunt's apartment while on home visits. After a 30-day evaluation in the hospital, he was transferred to the correctional setting in spite of a judge's recommendation that he be placed in a special therapeutic setting because of his serious psychiatric problems and his "insubstantial delinquency record."

Another child was psychiatrically hospitalized 8 times, then transferred to the correctional school. And still another youngster, who had spent 4 years in a psychiatric hospital because of dangerous psychotic behavior and evidence of neurological dysfunction, was ultimately sent to the correctional school when, on discharge from the hospital at age 12, he wandered the streets, grabbing at women's breasts. His hospital discharge summary indicated that he was returned home after 4 years in order that he not become "institutionalized."

These were but four of the many children who were sent to the secure unit of the correctional school and who had previously been in residential psychiatric care. We wondered what percentage of the children sent to this unit had previously been in psychiatric residential treatment or had been psychiatrically hospitalized.

METHOD

Our sample of incarcerated children consisted of the first 88 boys who were placed on the secure unit of a correctional school during an 18-month period of time. Admission to the unit was determined by school administrators and judges based on the severity of delinquent behaviors.

The major source was the correctional school record, which almost invariably contained information regarding previous placements. In fact, correctional school records often contained copies of actual hospital or residential facility clinical reports. In addition, the boys in the study were interviewed and, whenever possible, a parent or guardian was contacted in order to verify information.

FINDINGS

Of the 88 securely incarcerated boys, 52 (59.1%) had previously been either in residential psychiatric treatment or psychiatrically hospitalized. Twenty-nine children had been in residential psychiatric treatment only; 9 children had been psychiatrically hospitalized only; and an additional 14 children had been both psychiatrically hospitalized and in residential psychiatric treatment.

In addition to having been psychiatrically hospitalized and/or in residential treatment, 28 of the 52 treated children had also spent time in foster homes or group homes. Only 9 of the 88 boys had been in foster or groups homes only. Twenty-seven boys had never been placed outside their homes.

Considering, now, the entire sample of 88 boys, the average number of placements a child had experienced was 1.818. This average included those children who had never been placed outside their homes. When the mean number of placements for boys ever placed outside their homes was calculated, the average number of placements was 2.622.

DISCUSSION

Our present data indicate that many seriously delinquent incarcerated adolescents have, during childhood, manifested signs and symptoms of severe psychopathology leading to inpatient psychiatric care. Many had also spent time in foster or group homes, which suggests that their parents were often unable to care for them. These epidemiological findings are consistent with two of our previously reported findings. First, we found that many delinquents were the children of seriously impaired parents (10). Second, we found that the majority of violent incarcerated delinquent boys whom we studied suffered from a variety of neuropsychiatric disorders that impaired their ability to adapt appropriately to their environments (11). The finding that 59.1% of the incarcerated boys had, prior to incarceration, required residential psychiatric care indicates that clinicians other than ourselves recognized the degree of psychiatric impairment in this population. In fact, they had made the effort to obtain residential treatment for these children, an indication of their concern.

One must therefore ask why these seriously disturbed youngsters were subsequently transferred to a correctional facility. A review of the children's early clinical records revealed that most of the youngsters with some psychotic symptoms and/or signs of neuro-

logical impairment posed serious behavior problems from early childhood onward. Nevertheless, as small children they were able to secure acceptance at residential facilities and hospitals. As these children matured physically, they continued to pose the same kinds of behavior problems that they had manifested earlier. Although in a few cases dramatic behavioral changes in adolescence could be documented, for the most part assaultiveness, temper tantrums, firesetting, and stealing were long-standing problems that during early childhood, along with neurological and often psychotic symptoms, were recognized as manifestations of psychopathology and were handled within the therapeutic settings. It was only when a child's increasing size made his aberrant behaviors more threatening to staff and other children that he was discharged to his home or transferred to the correctional school. The seriously disturbed adolescent was perceived as more violent and, indeed, his outbursts were potentially more dangerous because of his increased strength.

Discharge to the child's home often had the same effect as transfer to corrections—that is, parents who had been unable to manage their children when the children were younger were no better equipped to deal with the youngsters during adolescence. Hence, discharged children came into conflict with the law and eventually made their way to corrections. Noteworthy was the tendency of hospitals and treatment centers to change diagnoses at the time a child reached adolescence, although the child's symptoms remained relatively the same as they had been in childhood. Thus, children formerly given a diagnosis of borderline psychotic or minimally brain damaged were redefined as "aggressive acting out" or "antisocial" adolescents. In one instance, even previously diagnosed psychomotor epilepsy in a child with a documented temporal lobe focus of abnormality was rediagnosed as "explosive personality" for purposes of transfer. In essence, potentially treatable disorders such as schizophrenia, minimal brain dysfunction, and epilepsy in children with aggressive symptoms were redefined as ostensibly less treatable sociopathic disorders in order to justify the children's transfer to the correctional school.

The finding that seriously psychiatrically disturbed children are often transferred from therapeutic settings to correctional facilities at the onset of adolescence is particularly ominous today, when hospital beds are decreasing in number and the criteria for the psychiatric hospitalization of children are becoming increasingly strict. In the recent past, psychiatrists and attorneys have focused much energy and attention on the rights of juveniles *not* to be hospitalized (e.g., the Mental Health Law Project) (12). However, little if any attention has been given to the rights of psychiatrically disturbed youngsters to continue to receive necessary residential or hospital care through adolescence, when their disturbed behaviors are acknowledged to be dangerous to others. Since the criteria for the incarceration of children are extremely lenient (a child need only have committed a nonstatus offense of one sort or another), we can expect even greater numbers of seriously disturbed children to be sent to correctional schools in the future. Tragically, once a child has been designated delinquent (much less incarcerated), it is almost impossible to reinstitute residential psychiatric treatment for him in a reputable facility.

The Psychiatrist's Role in Aerospace Operations

BY WILLIAM H. SLEDGE, M.D., AND COL. JAMES A. BOYDSTUN, MC, USAF

This paper presents two unique aspects of aerospace psychiatry: the influence of the specialized stressors and occupational requirements of an aviation career and the ambiguous role of the aerospace psychiatrist. Aerospace psychiatrists have multiple, sometimes conflicting, responsibilities to the organization and society (the social control task) and to the individual aviator (the humanistic and medical tasks). In the two case reports below the authors describe airmen who had vasovagal syncope and how the psychiatrist intervened and resolved these conflicting tasks.

Aerospace psychiatry is the practice of occupational psychiatry in the context of aviation and space operations. Two aspects of aerospace psychiatry present unique challenges to practitioners. First, the specialized occupational environment of aerospace operations entails particular psychosocial stresses, which result in a variety of altered priorities and paradoxes; for instance, benign medical disorders may have quite serious occupational implications. Second, the role of the psychiatrist is ambiguous because the psychiatrist must simultaneously serve multiple tasks, some of which may be in conflict.

AEROSPACE OPERATIONS AND STRESSORS ON AVIATORS

Advances in aerospace technology demand efficient and error-free functioning because errors are especially amplified by the high-performance capability of aircraft. Furthermore, the high-performance capability of aircraft creates conditions that have special stressors for the aviator. Some of these stressors are acceleration forces, transmeridian travel with jet lag, high-altitude flying, and flying in extremes of temperature. We will not address space travel here.

Presented at the 132nd annual meeting of the American Psychiatric Association, Chicago, Ill., May 12-18, 1979. Received Sept. 4, 1979; revised March 15, 1980; accepted April 14, 1980.

From the Department of Psychiatry, Yale University School of Medicine, New Haven, Conn. (Dr. Sledge), and Fairchild Air Force Base, Washington (Col. Boydstun).

An increased number and range of tasks can be performed by flight crews because of automated and computerized flight aids. However, the complexity of aircraft and the enormous increases in air traffic have resulted in more rigidly controlled safety requirements. These include precise procedures and regulations for negotiating weather and high-density traffic centers, more exacting medical surveillance of flight crew, and increased proficiency checks and adherence to training needs. Psychosocial factors of crew interaction, separation from family, fatigue-rest cycles, and time-zone travel are potential stressors. Consequently, professional aviators are caught in a series of demanding paradoxes; they must be able and willing to submit to numerous regulations, procedures, and rules in their professional lives, yet they must maintain a sense of responsibility and initiative in the execution of their work. They must be calm, thoughtful, and free of impulsive tendencies; however, they must be quick to react adaptively to emergent situations. Aviators must be able to tolerate stretches of long hours of work alternating with long periods of rest. Frequently, they and their families must be able to endure long periods of separation alternating with long periods of being idle at home. They must be able to make quick, effective decisions when given incomplete information, but they must always be looking for more facts about their present situation. They must also have a healthy, enduring love of flying tempered by a realistic respect for its dangers. They must be self-confident and convinced of their ability to survive dangerous situations; yet they must not be so grandiose that they take foolish chances or so unsure of themselves that they constantly must prove their mastery and invulnerability.

The typical flyer is achievement-oriented, with a high need to perform well. Competitive and aggressive needs are adaptively channeled into work and mastery of the flying environment (1, 2). The average flyer uses action to deal with ambiguity and psychic conflict and to achieve gratification. As a group, these men and women have obsessive-compulsive tendencies; however, these traits are usually flexibly deployed and do not necessarily represent neurotic conflicts or immutable styles.

Perhaps the most important personal trait for a flyer who wants a successful and safe aerospace career is motivation, particularly in terms of its coherence and fidelity with past experiences, its formal characteristics, and its content in organizing drives and needs

into appropriate adult activity (3). One theory (4) suggests that a successful flying career is an integration of infantile erotic and aggressive urges with the appropriate cognitive and affective attributes. The aircraft may become a powerful instrument of aggressive potential that is experienced unconsciously as a narcissistic extension of the self. The death-defying aspects of a flying career, coupled with the competitive rivalry with others, enhances the narcissistic gratification inherently involved in competent, masterful performance.

THE PSYCHIATRIST'S ROLE

Inevitably there will be failures and breakdowns in human functioning. When dysfunction occurs, the psychiatrist should be involved at three functional points in the aeromedical evaluation: diagnostic assessment from a clinical disease perspective, functional/adaptive assessment in terms of how the disorder has been influenced by and may continue to influence the job, and treatment.

In terms of role functioning, aerospace physicians are in a position of potential task conflict. Physicians who have primary contact with the patient must not only have patient care as their main function but they must also have a social control function whereby they work as agents of the organization to ensure mission completion and/or as protectors of public safety by identifying health conditions in the patient that threaten job functioning. This social control function of psychiatrists has been well characterized by Astrachan and associates (5). In addition the aerospace psychiatrist has the humanistic task of fostering the patient's development and opportunity and maximizing the patient's potential, as well as the medical task of diagnosing and treating the patient's disease; these may all conflict with the social control task.

Diagnostically, the aerospace psychiatrist assists other aerospace physicians and clinical specialists by helping them rule out functional disorders and clarify the relationships between psychosocial elements and altered biology. In addition to providing standard nosological or diagnostic categorization, the psychiatrist contributes by making a thorough evaluation of possible antecedent psychological and social factors in the onset of the disorder. In view of our research findings on syncope (6, 7), a careful appraisal of work-related stressors is particularly relevant.

As a behavioral scientist, the aerospace psychiatrist is in a good position to make a functional/adaptive assessment of how a particular disorder may influence job performance. The aerospace psychiatrist needs a clear understanding of possible psychosocial precipitants and the psychosocial consequences of the disorder. Ideally, the two perspectives on treatment outcome—the individual's interest in relief of suffering and the organization's interest in safe and reliable functioning—will not be in conflict. However, if there is conflict, the needs of the organization for safety and reliability must take precedence over the needs of the individual for employment and professional growth. This dilemma for the aerospace psychiatrist may occur in situations where the aviator has a form of intrapsychic conflict that is about to reach expression. Then the psychiatrist is faced with the problem of opting for either short-term public safety, by intervening to bolster the patient's repressive defenses, or a more therapeutic approach, by making the patient's conflict more manifest, which may lead to further temporary work dysfunction. Although this type of dilemma arises at times, usually the patient's interests and tolerance for psychological work will determine how the psychiatrist intervenes.

When the psychiatrist represents the needs of the organization, there are various potential problems in the interventions that stem directly from his or her social control task. These problems are most obviously clear in the doctor–patient relationship, in which the usual potential obstacles and resistances may be exacerbated by patient wariness and distrust. For instance, the patient may be reluctant to cooperate and will consciously withhold data that he or she thinks may be condemning in the eyes of the psychiatrist. Usually an explicit early acknowledgment of this process is helpful in enhancing meaningful collaboration. Most aviators fear they will be grounded for an obscure reason that they believe is irrelevant to their safe and reliable function. At the same time most of them are highly safety conscious and are not willing to fly with a condition that *they* believe is dangerous. Along these lines collaboration can usually be maintained. In more intermediate or long-term treatments in which exploration, uncovering, and insight are treatment goals, the treating physician's attitude toward the social control task must be kept very clear.

Another potential problem area is the psychiatrist's attitude toward the dual tasks of individual care and social control function. A balanced double perspective requires the psychiatrist to resist overidentifying with the patient at the expense of ignoring the organization's needs and to resist rigid application of organization rules (thereby prematurely foreclosing exploration) as a result of hostile countertransference feelings.

We will report two cases of vasovagal syncope to highlight the multiple aspects of the aerospace psychiatrist's functioning. Vasovagal syncope is a benign disorder from a health perspective, but it may present a threat to reliable professional functioning, depending on its context of onset and repetitions. There is good evidence that the onset of vasovagal syncope is dependent on a variety of psychosocial elements (6–8), including the specific context in which it occurs and broad nonspecific factors such as personality or character, antecedent psychological stress, negative feelings about work, and illness.

CASE REPORTS

Case 1. Mr. A, in his mid 20s, was a fighter jet pilot who fainted while having his blood pressure taken during an annual physical examination. A thorough medical and neurological workup revealed no disease or pathological condition as the basis for his fainting. He had fainted previously during an annual flight physical examination, and throughout his life medical procedures had made him uneasy. Furthermore, watching others clean and dress killed game after hunting made him queasy. However, he had been in situations where he and/or others had been injured or in pain and had had no syncope-like symptoms, for instance, viewing a dead friend's body and participating in his child's birth. There had been no clear psychosocial antecedents such as separations, loss, or job stress before this latest episode.

He gave a history of unconflicted competition and ambition to do well. Mr. A impressed the examining Air Force psychiatrist as an active, outgoing, action-oriented man. He had had a successful flying career, and his interest in and motivation for a flying career seemed to be appropriate and well integrated.

Although intially somewhat wary, Mr. A was able to appreciate during the course of several interviews with the examiner how physical manipulation of his body, however benign, together with a stance of enforced passivity and resignation were critical antecedents in his syncopal episodes. He was able to overcome this particular situation by assuming a more active orientation toward the numerous medical procedures and examinations being carried out during his aeromedical evaluation. An in-depth understanding of the dynamics of his "neurosis" was not attempted.

Although there were neurotic components in Mr. A's fainting response, this aspect of his psychopathology seemed discrete and limited and did not interfere with his flying; furthermore, the condition seemed influenced by education. It was recommended that Mr. A return to his flying duties.

In this case the psychiatrist was able to support the diagnosis of vasovagal syncope and rule out psychosocial factors that may have interfered with continuing job reliability and safe functioning. Furthermore, Mr. A and the psychiatrist were able to elaborate an understanding of the important psychodynamic elements in his syncopal episodes so that he was able to do something about the problem. His recurrent syncope was believed to be occupationally benign.

Case 2. Mr. B, a navigator in his mid 20s, fainted during a venipuncture procedure during an annual flight physical examination. A thorough physical and neurological evaluation revealed no somatic pathological basis for the syncopal episode. He had fainted three times before during medical or dental procedures that entailed receiving an injection. He almost fainted on many other occasions: during his wife's labor when she received an injection, when he came upon an accident and saw people injured and bleeding, and when he saw two people killed. Furthermore, he had had in-flight episodes of syncope-like symptoms during a variety of emergent and dangerous in-flight events, but he had never lost consciousness at these times.

Although there were no discrete antecedent psychosocial stressors before his last episode of fainting, Mr. B indicated that he had grave reservations about his suitability for a flying career. He wanted to serve out his commitment, but he found the work tedious, unfulfilling, dangerous, and frightening. During the evaluation he was found to be perfectionistic, overly conscientious, and severe with himself. He was not clinically depressed.

Mr. B was grounded and disqualified from flying on the basis of his recurrent episodes of syncope against the background of inflight episodes, conflicted feelings about his work, and questions about motivation for a flying career as a navigator. He was opposed consciously to the grounding and refused to accept a trial of psychotherapy after which time he could be reevaluated. The psychiatrist, therefore, recommended he be disqualified for flying. The social control function took precedence.

DISCUSSION

These two patients resembled one another superficially, but the relationship of the illness to flying was different. In both cases the psychiatrist was able to support the diagnosis of vasovagal syncope and make an assessment of the importance of antecedent psychosocial factors. Mr. A did not have a significant work-related dysfunction, and there were no apparent secondary gain benefits. The conflict was dealt with through rationalization and education. This approach permitted Mr. A to establish mastery over his symptoms, but he probably had no insight in the usual psychotherapeutic sense. The benign disorder of vasovagal syncope presented a possible threat to Mr. A's reliability as an aviator. The psychiatrist's assessment, however, suggested a focal neurotic process concerning enforced passivity during medical examinations; it did not reveal a dysfunctional response to the psychosocial stressors of an aviation career nor an inappropriate or conflicted motivation for a flying career. There was no task conflict for the psychiatrist.

Mr. B's medically benign disorder of vasovagal syncope did pose a threat to operational reliability and safety. The psychiatrist's evaluation revealed a more diffuse neurotic process involving a strong vagal response to many situations that were perceived as threatening, at least unconsciously, and that could not be countered. Furthermore this neurotic process was sensitive to the dangers and stressors of a flying career. He had an additional problem of conflicted motivation for flying and a character structure that compounded these problems. In Mr. B's case the psychiatrist experienced an element of task conflict: his social control function dictated that this patient be grounded and the humanistic function pointed toward trying to make it possible to work out his problems. The social control function clearly took precedence when Mr. B refused to accept grounding and a trial of psychotherapy.

The primary function of the psychiatrist who works as a part of the aeromedical evaluation process is to assess the relation of the patient's disorder to the occupation's psychosocial stressors and to assess how

the disorder relates to occupational functioning. In order to do this work effectively, the aerospace psychiatrist must not only know the aviator's character, motivation, psychopathology, and life events, but he must also understand the unique characteristics of aerospace operations. Furthermore, aerospace psychiatrists must be aware of the ambiguity of their own role in that they have responsibilities to the organization and society (the social control task) and to the aviator (the humanistic and medical tasks).

Psychiatric Participation in the Hootch Case: Effects on Alaska Native Education

BY JOSEPH D. BLOOM, M.D., AND JACQUELINE L. BLOOM, M.S.

The Hootch case was a class action suit that established the right of Alaska Native students to attend secondary school in their home communities. The authors review the history of Native education, give the background of the suit, and present behavioral science data on school adjustment of Alaska Natives and American Indian students. These data, included in an amicus curiae brief, were incorporated into the court decision. The authors consider this case a positive example of psychiatric involvement in social policy matters.

The 1972 case of *Molly Hootch et al v Alaska State-Operated School System* (1) dramatically changed secondary education for Alaska Native students. In this paper we will review the history of the educational system for Alaska Native students, including the problems that led to the Hootch case, and will focus on the psychosocial effects of this system of education.

The Hootch case was a class action suit brought by Molly Hootch, a representative of Alaska Native village adolescents, who was attempting to secure educational opportunities for them. Specifically, Hootch and her fellow students were seeking to establish their right to attend secondary school in their home communities. The case involved no direct psychiatric testimony. However, psychiatric data on the effects of the secondary education system on Alaska Native students were provided through an amicus curiae brief that was submitted jointly by the local Alaskan chapters of the American Psychiatric Association, the Alaska State Medical Association, and the American Academy of Pediatrics (2).

ALASKAN NATIVE SECONDARY EDUCATION: HISTORICAL DEVELOPMENT

In 1884, 17 years after the Alaska purchase, Congress passed legislation that incorporated the new territory into the United States as an administrative juris-

Received April 3, 1979; revised Oct. 22, 1979; accepted Dec. 4, 1979.

diction (3). Within the confines of this act, Congress set up an administrative procedure for the provision of education to the newly formed territory through the Bureau of Education. The first agent of the United States Bureau of Education in the territory was Dr. Sheldon Jackson, a Presbyterian minister. Jackson sought to interest religious denominations in establishing church schools and missions throughout the territory. Jackson was instrumental in establishing the Moravians in southwest Alaska, the Catholics on the Yukon, the Episcopalians at Point Hope, the Presbyterians in Barrow, the Congregationalists at Wales, and the Friends at Kotzebue. In 1905 Congress combined the educational programs for Alaska Natives with those for American Indians in a law stating the Alaska students would have the right to enroll in any of the boarding schools established for American Indian children. The government gradually discontinued supporting church-run schools and began constructing village-based day schools. In 1931 administration of the education programs passed from the Bureau of Education to the Bureau of Indian Affairs within the Department of Interior. From this time until World War II availability of grade school education was still limited, and secondary education was almost nonexistent for the Native population.

After the war, government services in Alaska accelerated rapidly. In 1955 health care was shifted from the Bureau of Indian Affairs to a newly created health authority within the U.S. Public Health Service. This agency was created because of the dire health status of the Native people, who were plagued by epidemically high rates of tuberculosis. The introduction of antituberculosis medication together with a vigorous medical program brought the disease under control rapidly. By the late 1950s and early 1960s the population was increasing at a dramatic rate; during the 1950–1960 decade the population increased 27% (4). This population explosion greatly affected the resources of the educational system in the late 1960s and in the 1970s.

The educational system developed rapidly from 1950 to 1975. Day schools were built in villages and teachers encouraged students to go on to high school. To do so meant that the majority of students had to leave their home communities and reside at Mt. Edgecumbe School at Sitka, in southeast Alaska. As the demand for places in school increased, students were sent further away to schools within the larger Bureau of Indian Affairs system. In the late 1960s students from Alaska were placed in boarding schools at Chemawa, Oregon, and at Chilaco, Oklahoma.

Statehood was granted Alaska in 1959. Within a decade significant changes were made in the system of secondary education. Unlike most reservation Indians, the Alaska Native peoples had full equality under the Alaska constitution. The state of Alaska was thus responsible for providing educational programs for Native peoples just as it provided them for other residents. The Bureau of Indian Affairs programs were gradually transferred to the state of Alaska. Although there is still a dual educational system, the state has increasingly assumed the leadership in establishing programs and policy. The state moved vigorously into its own version of boarding school education. All high school students remained in Alaska, and secondary education was provided through a network of boarding programs both rural and urban.

During the decade from 1965 to 1975 new schools were built. Existing school districts, like Anchorage, developed programs for Native students within urban high schools. Students were kept in Alaska but were in a hodgepodge of federal, state, and local jurisdictions, which had limited coordination. Students, especially troubled students, often rode a circuit from one high school to another. Many rural boarding programs were located in rural transitional towns such as Bethel or Nome. Because these towns were in transition from villages to cities (5–7), their social climate generated problems for many adolescents. The urban boarding programs were more stable, but the urban schools were almost universally unprepared for large numbers of Native students. In addition, the private boarding homes were poorly screened and poorly supervised by state agencies. Thus, although the students had been separated from the Bureau of Indian Affairs secondary school system, the learning environment had not really improved.

In 1971 Congress passed the Alaska Native Claims Settlement Act (8). The act extinguished the Native claims against the federal government with a cash and land payment to the Native groups. Regional Native corporations were organized to handle the settlement. The Claims Settlement Act focused on a regional entity for community organization and ultimately provided administrative structures that could be used for institutional change (9).

THE HOOTCH CASE

Molly Hootch was an Eskimo from Emmonok, a large village at the mouth of the Yukon River near the Bering Sea. In order to attend secondary school, Molly Hootch, as well as the other 3,000 Alaska Native school-age children, would have had to leave her home and family and travel a substantial distance to attend high school. The case was based on a constitutional argument that stated that the constitution of Alaska guaranteed public school as a "fundamental right to all Alaskan children, and further as a right it must be provided on equal terms to all children." The case was lost in the superior court in 1974 and was appealed immediately to the Alaska Supreme Court. The superior court's decision acknowledged that the state was obliged to make educational opportunities available to students and stated that it did so through

the state boarding programs. Availability of high school programs in every village was not regarded as a basic right and, further, was considered financially prohibitive.

In preparing their appeal to the Alaska Supreme Court the attorneys for the villagers asked the Alaska Psychiatric Association to detail the psychosocial effects of boarding school education on the children and their parents. Mental health professionals and educators had for years seen that the educational system resulted in dropouts, suicide attempts, antisocial acting out, alcohol problems, identity diffusion, poor vocational planning, and only a small number of students going on to advanced training institutions.

In the amicus brief a general statement was made regarding adolescent development in the context of family and cultural life. Given the cross-cultural problems faced by Alaska Native children, the maintenance of parent-child contact was viewed as crucial through the teenage years. The brief cited studies concerning the effects of boarding schools on Alaska Native students. Kraus (10) found a definite over-representation of younger people in suicide attempts and suicide. He concluded that school separation was a definite factor in the suicide problem. Kleinfeld (11, 12) studied Eskimo students in four different school environments: an urban boarding home program, a rural boarding home program, a rural transitional town boarding school, and a village-based church-affiliated school. Using a variety of measures, Kleinfeld found that rates of emotional disturbance were high in all of the schools but particularly so in the two rural town programs and the urban boarding school. The amicus brief concluded by supporting the position of the plaintiffs against the State Department of Education and recommending to the state supreme court that secondary education be moved to the villages.

The suit was settled in 1976 through a negotiated agreement in favor of the village children. The combination of the original constitutional issues and the behavioral science data was a crucial element in the court's findings, as shown by its decree:

> Members of the plaintiff class enrolled in the boarding program have experienced accelerated drop-out rates, psychological and social problems, including disruption of family life and loss of identity, and failure to live up to educational potential. Studies of drop-out rates indicate far higher rates among Native children attending boarding programs than among Native children residing at home while attending secondary school. . . . Also the sending of Native children to secondary schools outside of their villages has had harmful effects on village cultural and family life and on the student's relationship to each. When the student who attends a boarding program returns to his village in the summer, he finds it difficult to readjust to village life because of the increasing differences between himself and the other members of his village. He is unable to fully identify with either the town or village way of life. Such students are in the process of becoming what anthropologists term "marginal. . . ." (1)

The language cited reflects the court's consideration of the views expressed in the amicus brief. *Indian Family Defense* (13), published by the Association on American Indian Affairs, cited the conclusion of the case as a historic victory affecting Native American children and looked for ramifications that would affect Native American boarding programs in other areas of the United States.

DISCUSSION

The outcome of the Hootch case was based on the state's recognition of the right of children to be educated in their home villages. The court case was able to focus in one forum both the constitutional and human outcome arguments. It is interesting that most of the same issues have long been known and debated in professional circles and within government. Krush and associates (14) coined the term "psychological nomadism" to describe the objectless, anomic existence characteristic of the boarding school experience. Hammerschlag and associates (15) described one southwestern boarding school and concluded that the educational system contributed to the sense of powerlessness and government dependency so prevalent among Indian peoples. Shore and Levy[1] described high dropout rates in a northwest Indian boarding school. They reported a dropout rate of 26% in 1970–1971. In another report, Shore (16) described the difficulties and frustrations involved in providing mental health consultation in the same boarding school. In an editorial in the *American Journal of Psychiatry* (17) Beiser pointed to the problems of Indian boarding schools and called for changes in programs that separated children from their parents. Based on data gathered from a boarding school project in the southwest (18), the editorial suggested improvements in the schools that involved improving staff/pupil ratios by employing more Indian persons in dormitories and as instructional aides. The ill effects of Indian boarding schools were summarized in a publication of the Association on American Indian Affairs titled *The Destruction of American Indian Families* (19).

From the perspective of the physicians and behavioral scientists involved in the amicus brief the outcome was very positive. As indicated above, clinicians had for years seen a wide variety of problems that attested to the negative influence of the educational system on both Alaska Native and Indian children. In Alaska it had become painfully clear that the system of education was not improving after the state moved to

[1] J. Shore, J. Levy: Dropout epidemic at an Indian boarding school. Department of Psychiatry, University of Oregon Health Sciences Center, 1975 (processed)

replace the Bureau of Indian Affairs as the dominant system in education.

The amicus brief offered a vehicle by which scientific evidence directly effected a major social change. An implied hypothesis in this report is that the willingness to be involved in court proceedings of this type is an important consideration for psychiatrists interested in social change, decreased psychiatric morbidity, and in primary prevention. Psychiatry's involvement in social issues is certainly widely debated today within the profession. We consider the material described in this paper as a positive example of psychiatric participation in an attempt to solve an important social problem affecting the next generation of Alaska Native students.

Treatment of Depression in the Medically Ill Elderly with Methylphenidate

BY WAYNE KATON, M.D., AND MURRAY RASKIND, M.D.

Three depressed geriatric patients had a marked therapeutic response to the psychostimulant drug methylphenidate. These patients either had been unable to tolerate tricyclic antidepressants or had a medical illness that contraindicated tricyclic therapy. The lack of adverse effects in our elderly patients and methylphenidate's effectiveness as an antidepressant were consistent with the findings of other investigators. These results suggest that psychostimulants deserve further evaluation as antidepressant agents in the geriatric population.

Although tricyclic antidepressants are the drugs of choice in the psychopharmacologic management of depression (1), their adverse anticholinergic and cardiovascular effects can limit their usefulness in elderly depressed patients, particularly those suffering from a concomitant serious medical illness. Given the high prevalence of depression in the elderly (2), finding an antidepressant regimen for geriatric patients who cannot tolerate tricyclics is a significant problem. One seldom considered alternative psychopharmacologic agent is methylphenidate, one of the psychostimulant drugs. Psychostimulants were briefly used as antidepressants before the introduction of tricyclics, but legitimate questions concerning long-term efficacy and potential for drug abuse contributed to a marked decrease in their use as antidepressants. On the other hand, the psychostimulants are effective and widely used in child psychiatry in the long-term management of the minimal brain dysfunction syndrome (3). In the pediatric population, adverse effects, tolerance, and drug abuse have not been significant problems (4, 5).

The usefulness and safety of psychostimulants in the pediatric population suggest that age may be an important variable in the effectiveness of this class of drug. In fact, several reports suggest that psychostimulants may have a place in the psychopharmacology of another special age group, the geriatric population. In a placebo-controlled but nonblind study (6), methylphenidate was significantly superior to placebo in the treatment of 54 elderly patients suffering from depression. Two studies have demonstrated methylphenidate to be effective in treating secondary depression in patients in whom the affective signs and symptoms were superimposed on an underlying dementia (chronic organic brain syndrome). In the first study (7), depressed dementia patients responded better to methylphenidate than they did to the tricyclic antidepressant protriptyline. In the second (8), methylphenidate was compared to placebo in the treatment of a large group of depressed elderly patients with underlying dementia. Methylphenidate was clearly superior to placebo in this double-blind 8-week study, and the methylphenidate group was remarkably free of significant adverse effects. Faced with the dilemma of instituting an effective therapeutic regimen for elderly depressed patients who were intolerant of tricyclic antidepressants, we elected to treat several of these patients with methylphenidate. Following are illustrative case reports.

CASE REPORTS

Case 1. Mr. A, an 82-year-old retired professor, had a one-year history of poor mental concentration, loss of interest in his environment, decreased energy, insomnia, episodes of tearfulness and pessimism, decreased appetite, and an insidious 7-kg weight loss. Psychometric testing and a complete neurological evaluation showed his cognitive functioning to be within normal limits. His primary physician had diagnosed depression and had prescribed amitriptyline, 50 mg/day. Unfortunately, acute urinary retention had developed and amitriptyline treatment was discontinued, without any change in Mr. A's psychiatric status. Supportive psychotherapy by the primary physician had also failed to alleviate Mr. A's symptoms, and he was referred for psychiatric evaluation.

We confirmed the diagnosis of depression and elected to start a course of desipramine. We hoped that the relatively low anticholinergic activity of desipramine would lower the risk of urinary retention (9). Unfortunately, after the dose had been gradually increased to 75 mg/day over 2 weeks, urinary retention again developed, without improvement in Mr. A's depressive signs and symptoms. After a drug-free

period of 10 days, we prescribed 10 mg of methylphenidate twice a day. Two days later Mr. A reported that his mood was brighter and his ability to concentrate on everyday tasks was improved. Over the subsequent month his mood, enthusiasm, energy, and appetite markedly improved and he returned to part-time work. Methylphenidate treatment was continued for another 3 months and Mr. A maintained his therapeutic gains. Urinary retention or hesitancy were not problems, and there was no suggestion of psychostimulant habituation or abuse. Methylphenidate was discontinued after the 4-month treatment course and Mr. A remained free of signs and symptoms of depression at 1-year follow-up.

Case 2. Ms. B, a 73-year-old nursing home resident, had adult onset diabetes mellitus and bilateral amputations below the knee for peripheral vascular disease. She developed saddened mood, decreased appetite, weight loss, social withdrawal, and loss of interest in her usual activities over a 3-month period. Her private physician prescribed a 4-week course of imipramine, 100 mg/day in divided doses. The imipramine regimen was associated with unpleasant tremor, constipation, nocturnal sweats, and increased dysphoria. Imipramine treatment was discontinued and amitriptyline was prescribed at 75 mg/day in divided doses. During the subsequent week Ms. B became increasingly lethargic and fell twice from her chair. Severe orthostatic hypotension was documented at the time of her falls and treament with amitriptyline was discontinued, with no evident improvement of her depression. After a 1-week drug-free interval, we began to administer methylphenidate, 10 mg twice per day. Ms. B noted an increased sense of well-being within 3 days and the nursing staff reported that she had increased energy, brightened mood, and increased participation in social activities. Over the next month Ms. B's signs and symptoms of depression resolved and she was judged to have returned to her previous level of function. Methylphenidate treatment was continued for another 2 months. During treatment Ms. B's blood pressure was stable and she did not experience any adverse effects from the methylphenidate. She was free of signs and symptoms of depression at 6-month follow-up.

Case 3. Ms. C, an 85-year-old woman, was hospitalized for treatment of a dislocated right hip suffered in a motor vehicle accident. She was withdrawn, apathetic, and somnolent. Her primary physician became increasingly concerned about her inadequate caloric intake, progressive weight loss, and refusal to participate in physical rehabilitation. After a thorough medical and neurologic workup failed to provide an explanation for her deteriorating condition, we felt that depression most likely was responsible for Ms. C's symptoms. Although both Ms. C and her husband denied that she had a history of affective disorder, they did acknowledge that she had been much less active and enthusiastic about general activities over the past 2 years, after a traumatic fall in her bathtub. Her husband stated that she was "just getting back to herself" when the motor vehicle accident occurred. During psychiatric examination Ms. C appeared lethargic, apathetic, and depressed and had psychomotor retardation and increased latency of response. She was fully oriented, her past and present memory were normal, and she interpreted proverbs well. Several times during the examination she stated that she was very tired and needed to be left alone.

Electrocardiogram revealed first-degree atrioventricular block and a right bundle branch intraventricular block. Ms. C's primary physician felt that the cardiac conduction abnormalities contraindicated the use of tricyclic antidepressants. Therefore methylphenidate was prescribed at 10 mg twice per day. Within 3 days Ms. C was eating well participating in physical activity, and sitting up most of the day. She was alert, her mood was much improved, and she showed renewed interest in her rehabilitation and discharge from the hospital. She left the hospital 10 days later to continue her convalescence in an intermediate care facility, and her improvement in mood and activity level persisted.

DISCUSSION

We have presented three cases of depressed geriatric patients who either could not tolerate tricyclic antidepressants or whose medical status was felt to contraindicate the use of tricyclics. Each of these patients appeared to have a marked therapeutic response to low-dose methylphenidate. Although positive case reports certainly do not establish the antidepressant efficacy of a drug, these three cases illustrate several aspects of treatment with methylphenidate which suggest that this drug deserves more careful scrutiny as an antidepressant agent in the geriatric population. Of note was the rapidity of the therapeutic response, in each case beginning during the first few days of treatment. Of perhaps greater importance was the absence of significant adverse effects from methylphenidate in these three patients. The same patients who either could not tolerate tricyclic antidepressants or for whom tricyclics were felt to be contraindicated easily tolerated a course of low-dose methylphenidate. We did not observe the adverse effects that have been attributed to psychostimulants (10), such as appetite suppression, hypertension, palpitations, cardiac arrhythmias, nervousness, headaches, dyskinesias, precipitation of paranoid ideation or overt psychosis, insomnia, rapid tolerance to euphoriant effects, and abuse of these agents. This absence of adverse effects may have been fortuitous or secondary to the low dose of medication, but it is consistent with the low incidence of adverse effects secondary to methylphenidate in previous geriatric studies (6–8, 11–14).

Ms. C demonstrated another property of the psychostimulants, which Hackett and Draper (11) described as particularly relevant to consultation-liaison psychiatry. This property is its usefulness in the differentiation of depression from enfeebling medical illness. A sustained improvement of mood, energy, and function with psychostimulant therapy suggests a large component of reversible depression in the medically ill.

Before the initiation of treatment with methylphenidate, the consulting psychiatrist attempted supportive psychotherapy in each of the three cases, with little benefit. However, after methylphenidate treatment had begun the patients' affects brightened and their energy levels increased, which facilitated the formation of a strong therapeutic alliance with the psychiatrist

and subsequent beneficial supportive psychotherapy. Jacobson (6) also noted that methylphenidate increased the efficacy of psychotherapy in depressed geriatric patients.

Our suggestion that methyphenidate be considered as a therapeutic approach to the patient who cannot tolerate tricyclic antidepressants is not meant to imply that other approaches do not exist. Electroconvulsive therapy is effective and reasonably safe for severely depressed geriatric patients and may even be the treatment of choice for those with clear-cut delusions or for those whose nutritional status cannot be maintained (15). On the other hand, posttreatment memory impairment can be a problem in the elderly, and the idea of electroconvulsive therapy is frequently unpalatable to either the patient or the patient's family. Also, the use of electroconvulsive therapy is often administratively difficult in the nursing home population because the patient would have to be transferred to a hospital and would require the services of an anesthesiologist. The monoamine oxidase inhibitor drugs are effective antidepressants, but the risk of serious adverse effects has led several authorities (16) to discourage the use of monoamine oxidase inhibitors in the elderly patient.

Our data and those of earlier investigators suggest that methylphenidate is a reasonable candidate for closer scrutiny as an antidepressant drug for the elderly depressed patient. Well-designed clinical studies would clarify the role of methylphenidate in this important patient group, especially in those who cannot tolerate tricyclic antidepressants.

Traumatic Neurosis in the Etiology of Alcoholism: Viet Nam Combat and Other Trauma

BY ROY B. LACOURSIERE, M.D., KENNETH E. GODFREY, M.D., AND LORNE M. RUBY, M.D.

Traumatic neurosis from Viet Nam combat or other sources includes many symptoms that can be effectively self-medicated with alcohol, at least initially. These symptoms include chronic anxiety and restlessness, insomnia, and recurrent frightening dreams. Repeated self-medication with alcohol results in tolerance and a need to increase the amount consumed. Attempts to decrease consumption or to abstain can lead to alcohol withdrawal symptoms similar to and exacerbating the initial symptoms of traumatic neurosis. Continuing alcohol use, with the establishment of a vicious circle, can follow. The authors present three case examples. They note that treatment of alcoholism under the conditions described requires specific attention to the underlying traumatic neurosis.

> Wine drunk with an equal quantity of water puts away anxiety and terrors.
>
> —Hippocrates, *Aphorisms*

The perspective of a Veterans Administration chemical abuse program has allowed us to observe a relationship between traumatic neurosis and alcoholism in some patients. This relationship is seen in Viet Nam combat-traumatized veterans and in other combat veterans, and may well occur in association with traumatic neurosis from noncombat sources. A variety of postcombat syndromes have been described (1, 2); the clinical picture is often not "pure." Of particular note in this paper are the symptoms associated with classical traumatic war neurosis, i.e., chronic and at least moderately severe anxiety; recurrent frightening dreams, usually about the traumatic event or events; and insomnia, irritability, agitation, depression, and somatic symptoms and preoccupations. Often the insomnia is secondary to the feared dreams. Various abusable substances can be used to suppress these symptoms, e.g., minor tranquilizers, barbiturates, and alcohol. In this report we focus on alcohol, a substance readily available and at least implicitly encouraged among armed forces personnel in the United States (3).

The acute administration of alcohol relieves many of the symptoms of classical traumatic neurosis. It is effective in inducing sleep and suppressing anxiety and can ease muscle tension and sometimes depression, irritability, and agitation. In most patients alcohol initially suppresses REM sleep (4–6), with which most posttraumatic terrifying dreams are associated (7). (It apparently does not provide such suppression in all patients [8].) Some of these terrifying dreams are probably stage IV night terrors; the effect of alcohol on them is not firmly established, but alcohol may have a suppressant effect similar to that of diazepam (7). The repeated drinking of alcohol leads to tolerance and the need to increase the amount consumed. Even then, with chronic alcohol use disturbing dreams can break through the suppressing effects (7). In addition, the abrupt cessation of significant drinking leads to its own problems. These are the well-known symptoms of the alcohol withdrawal syndrome and include many symptoms similar to those of traumatic neurosis, e.g., anxiety, motor restlessness, agitation, insomnia, and an increase in frightening dreams (4–6, 8). Thus, what can begin as innocent self-medication for symptoms of traumatic neurosis can lead to a vicious circle. Repetitive symptom reduction by means of alcohol leads to tolerance and an increase in alcohol consumption to maintain symptom reduction, which leads to problems from the alcohol use itself (e.g., hangovers, gastritis, marital difficulties, and arrests for driving while intoxicated) and attempts to reduce or abstain from alcohol consumption. This leads to the alcohol withdrawal syndrome, with an exacerbation of many of the initial traumatic neurosis symptoms; this stimulates further drinking, closing the vicious circle.

It is important to note here that the initial use of alcohol is effective self-medication for many posttraumatic symptoms. After chronic use, attempts to stop the self-medication lead to exacerbation of the initial symptoms. This use of alcohol is different in de-

The authors wish to thank the many veterans who through their difficulties have been our teachers.

gree, if not also in kind, from the more frequent use of alcohol to relieve general psychological dysphoria; in the latter case the cessation or decrease of chronic alcohol use does not lead to withdrawal symptoms that are as synergistic with the initial psychological difficulties. In addition, alcoholism secondary to traumatic neurosis calls for particular therapeutic strategies with these alcoholic patients.

CASE REPORTS

The patients described here were all treated in our intensive residential alcohol rehabilitation program. The first patient had a classic traumatic neurosis; the second patient showed symptoms of traumatic neurosis mixed with other postcombat symptoms (2); and the third patient had an attenuated traumatic neurosis that had persisted for over 30 years.

Case 1. Mr. A, a 30-year-old veteran, was admitted because of alcoholism associated with interpersonal, work, and health problems. Although well detoxified on admission, he was extremely anxious, restless, "couldn't remember" much of his background or experience in Viet Nam, and either kept considerably to himself or sought staff contact for a variety of physical and psychological complaints. He slept very poorly and had recurrent terrifying dreams.

Mr. A had been adopted as an infant, and his natural parents were unknown. His adoptive parents were free of alcoholism and had no history of psychiatric treatment. He reported that he drank during high school and used marijuana but that this had not created problems; his family corroborated this information. He entered the army at age 19 and was sent to Viet Nam as a foot soldier. While patrolling and preparing to settle for the night, his patrol of 27 members was ambushed by machine-gun fire and all but a few of his group were killed in a matter of seconds. No one who was hit survived. He and a few others at the end of the line of soldiers were not hit. He felt extremely helpless during this catastrophe. He was subsequently very "uptight" and began to be awakened regularly by terrifying dreams in which he relived the ambush. He began to try to go to bed later and later and used drugs and alcohol more extensively; he found they relaxed him and helped him sleep. After discharge from the service he ceased using most drugs except alcohol, but alcohol began to cause him progressively more problems. His admission to our unit was his second treatment program for alcoholism.

Mr. A's treatment with us included thrice-weekly psychotherapy using support and hypnotherapy focusing on relaxation, recall of the traumatic event, and some catharsis. As often occurs, the combat trauma was found to be related to prior experiences, including early childhood experiences of being helpless and overwhelmed; these experiences were also examined. Hydroxyzine, 50 mg three times a day, was used to help decrease the patient's extreme level of anxiety and marked resistance to exploring the traumatic events. With 2 months of treatment the patient's severe anxiety level abated considerably, and he slept well without frightening dreams. At discharge he was taking disulfiram and hydroxyzine and felt confident that he could manage without alcohol.

At follow-up a month later Mr. A was doing well, was sober, and, as his father reported, was "calmer than he's been in many years." His sleep continued to be very much improved, although he had had at least one night of disturbing dreams.

Case 2. Mr. B, a 29-year-old veteran, was admitted for treatment of alcoholism after prior detoxification in another hospital. On admission he was depressed, had fears of attack and death, was concerned over losing control of his anger, and described repetitive frightening dreams showing the faces of two Vietnamese he had killed. He described himself as "a small town boy" jolted by his military experience.

Mr. B's family background showed no evidence of alcoholism or psychiatric problems. He was in the military from ages 18 to 20 and began drinking significant amounts of alcohol toward the end of that time. He felt that drinking represented an attempt to cope with his fears of imminent attack and death, sorrow over the loss of friends, rage at the Vietnamese enemy, and guilt over his killing others. He said that he had problems from alcohol within his first year of drinking. He acknowledged experimenting with other substances, but without difficulties. Before his treatment with us he had been detoxified from alcohol in 1974 and 1975.

Mr. B's treatment on our unit included short-term individual and group psychotherapy with emphasis on exploration, catharsis, and reintegration of his Viet Nam experiences. By discharge he was much improved and was free of frightening dreams. No follow-up data were available.

Case 3. Mr. C, a 59-year-old World War II fighter pilot, was intoxicated when admitted for his first treatment for alcoholism. Following detoxification he was anxious, restless, dejected, and complained of poor sleep with recurrent frightening dreams.

Mr. C's history showed that his father had had problems with alcohol beginning when the patient was a teenager. While in the service the patient was shot down over Japan shortly before the end of the war and was beaten by peasants before being taken into custody by the local police. From that time onward he had a recurrent dream that awakened him in terror in a cold sweat just at the point of being shot down. He said he used alcohol to sleep, to avoid dreaming, and "to settle my nerves." Although alcohol did not fully stop the dreams, when he tried to abstain from drinking the dreams became worse and he lost more sleep.

Mr. C's treatment included hypnotherapy with abreaction of the traumatic event after abreaction of earlier traumatic life experiences related to the combat trauma. He progressively slept better and soon slept through the night without frightening dreams. His overall condition in spite of its long history was much improved at discharge. On follow-up several weeks later his wife noted many ways in which he had changed; he was sociable, patient, had a sense of humor, was relaxed, and slept well. He was maintaining sobriety.

DISCUSSION

We do not wish to imply that other factors may not also have had important etiological significance in these cases of alcoholism. However, from our evaluation the traumatic neurosis-type symptoms were crucial and precipitating causes, and diligent attention needed to be directed to them to satisfactorily treat the alcoholism. Whether or not we have obtained enduring and significant help for the patients' posttraumatic

symptoms or for the alcoholism remains to be seen, but it appears to us that a treatment approach for such cases of alcoholism which ignores the historical development will have less chance of success. The possibility remains that alcoholism which begins largely secondary to a traumatic experience might persist after the traumatic neurosis is adequately treated. This is a researchable question.

The relationship between traumatic neurosis and alcoholism appears not to have been previously recorded in the psychiatric literature. Our computer searches of the literature for the past 10 years failed to find any material on this subject, as did an examination of older war-related literature (but see hints in reference 1, p. 413). It is hoped that our drawing attention to this relationship may encourage others to carefully look for it, provide appropriate treatment, and perhaps further study this area.

A Multi-Tiered Screening System for the Least Restrictive Setting

BY RICHARD H. ALLEN, DR.P.H., MAXINE WEINMAN, DR.P.H., RONALD LORIMOR, PH.D., AND JAMES L. CLAGHORN, M.D.

The authors evaluated the placement process in a large psychiatric facility with both inpatient and outpatient services. They examined 71 inpatient and 90 outpatient new admissions using standardized tests of psychopathology and sociodemographic status. After correcting for response bias, the authors found, in contrast to other studies, that the level of morbidity in the inpatient service was significantly different from that in the outpatient unit. The measures of sociodemographic data indicate that inpatients were more dependent on social support systems and that this finding was not influenced by response bias.

A psychiatrist's decision to hospitalize a patient is a profound moment in that patient's life. Apparent immediate medical desirability notwithstanding, the patient will most assuredly experience the stigmatizing effects of psychiatric hospitalization. In contrast to outpatient placement, such an event can compromise a patient's effectiveness in securing employment, joining a union, or entering a trade or professional school. For these reasons, the process for hospitalization should be carefully designed to ensure that inpatient placement is essential to the total well-being of the patient. To that end, a step has been interposed at our facility before hospitalization. Our facility requires that all patients who are hospitalized must have been interviewed first in an outpatient setting. Those patients who might be treated effectively in an outpatient setting are then so assigned.

Several authors (1, 2) have posited that precise criteria should be established for psychiatric inpatient placement because standards for hospitalization are seldom explicit. Such criteria for admission would logically include severity of illness as well as usefulness of programs unique to the inpatient setting for the patient. Measurement of the severity of illness, however,

is complicated by the tendency for patients to exaggerate or minimize their reports of symptoms (3). This creates a diagnostic dilemma for the clinician and an interpretation hazard for the psychometrist. The extent to which this distortion is systematic lends itself to examination focusing particularly on the way it blurs discrimination between groups and interferes with appropriate placement.

In this investigation we examined the placement process of a large psychiatric institute with both inpatient and outpatient facilities. The purpose of the study was to show whether placement was justified by differences in standardized tests of personal and social functioning. Additionally, we examined the hypothesis that distortions in symptom reporting do occur and that this distortion is a function of response bias. We have defined response bias as the tendency to minimize or exaggerate the presence of symptoms; therefore, we analyzed the influence of response bias in interpreting the differences.

METHOD

Setting

The Texas Research Institute of Mental Sciences is the research and training arm of the Texas Department of Mental Health and Mental Retardation. In order to satisfy its mission, the Texas Research Institute has established a broad-based service component that includes an inpatient unit and one of the largest outpatient departments in Texas. A patient's entry into the adult service involves evaluation at each stage of a three-tiered system that graduates from a paraprofessional level through the front-line therapist to the doctoral-level supervisor. Medical responsibility for each case is assigned to the psychiatrist attached to the unit.

The initial contact for services is made with a caseworker in the Information and Referral Service. The paraprofessional staff member at this critical juncture is familiar with criteria regarding appropriateness for admission to each of the adult service units. Following this contact, an appointment is made for the patient to be interviewed by a primary therapist from the adult outpatient unit. A psychiatrist reviews the information obtained by the primary therapist and, if appropriate, also interviews the patient. The decision as to placement of the patient is then made.

This course of events is followed, even for people who obviously require hospitalization, to comply with the state mental health commissioner's rule regarding outpatient evaluation for least restrictive setting. The rule was made in response to an increasing social conscience within the state department of mental health and was influenced by court precedents. It contains minimum guidelines for hospitalization that are used by the outpatient personnel in the placement decision process. These guidelines are as follows:

1. Both mental impairment or a reasonable presumption of mental impairment and social impairment may justify admission.
2. Evidence of the following *must be* documented: a) ideational or behavioral indications of dangerousness to self or others, b) need for planned psychiatric, medical, social, or psychological evaluation or treatment; special drug therapy; treatment requiring hospitalization or continuous skilled observation.
3. Evidence of the following *may be* present: a) impairment of social, familial, or occupational functioning of sufficient severity to require the structure or safety of inpatient services, b) failure of outpatient or extended care management, c) inability to meet one's own basic life and health needs, d) behavior "intolerable" to patient, family, or community, e) need to interrupt deleterious psychosocial interactions.

If a crisis exists, the entire review sequence is condensed into a single day. A request for emergency treatment is not, of itself, a sufficient criterion for crisis intervention. The working definition of "crisis" is based on the imminence of a bad experience for the patient or others. If harm may come within a 72-hour period, a crisis exists and immediate steps are taken. A primary therapist conducts a complete interview to answer the questions remaining from the briefer screening examination. The supervising psychiatrist then talks with the patient and conjointly with the therapist determines the appropriate disposition. On the average, a third of the crisis patients are hospitalized, a third receive intensive outpatient crisis intervention, and a third are referred to another clinic.

Subjects

The subjects for this study were 71 inpatient and 90 outpatient new admissions to the Texas Research Institute of Mental Sciences. Subjects were entered into the study sequentially. All patients who were able to respond to questions were asked to participate. In neither group was participation presented as part of a treatment program, and it was stated on the consent form that participation was voluntary. All of the subjects signed the consent form after the nature of the study had been explained.

The subjects displayed the spectrum of psychiatric problems seen at our facility, from severe psychoses to phobias and marital discord. Treatment is provided in the outpatient clinics according to the nature of the problems presented. The principal objective of the inpatient service is to stabilize the patient and return him or her to appropriate outpatient care as soon as possible. The length of stay is usually 20 to 25 days.

Instruments

The instruments in the study from which data were selected were the Denver Community Mental Health Questionnaire (4), a measure of effective level of personal and social functioning; the Mini-Mult (5), an ab-

TABLE 1
Unadjusted Means and Means Adjusted for L Scale for MMPI and Taylor Manifest Anxiety Scale Scores of 71 Inpatients and 90 Outpatients

Scale	Unadjusted Mean Score			Adjusted Mean Scores		
	Inpatients	Outpatients	Significance[a]	Inpatients	Outpatients	Significance[a]
MMPI						
Hypochondriasis	19.2	16.7	p<.02	19.4	16.5	p<.01
Depression	30.7	28.4	p<.06	31.1	28.0	p<.01

Taylor Manifest Anxiety Scale	27.0	25.8	n.s.	27.8	25.0	p<.09

[a]By two-tailed t test.

breviated version of the MMPI; and the Taylor Manifest Anxiety Scale (6), a measure of proneness to express anxiety.

Statistical Methods

A two-tailed t test was run to measure differences between inpatients and outpatients on each of the scales. To determine whether these differences would remain once response bias was controlled for, an analysis of covariance was performed using the lie (L) scale of the MMPI. The L scale items represent minor faults or foibles to which most people would readily admit and was designed as a correction factor for bias in socially desirable response sets. Burish and Houston (7) reported favorable construct validity for the L scale as a measure of defensive denial. "Defensive denial" is defined here as the unwillingness to admit minor faults or foibles. Following the analysis of covariance, the t tests were computed on the adjusted means and their values were compared with the unadjusted t values.

RESULTS

The first phase of this investigation was the determination of whether social support system differences were evident in inpatients compared with outpatients. On the basis of the hypothesis suggested by Mendel and Rapport (8) that social support resources are critical factors influencing the decision to hospitalize, inpatients were expected to have less access to these resources than did outpatients.

A t test analysis of social functioning compared the inpatient group with the outpatients on the scales of the Denver questionnaire. Differences that achieved or approached significance were on 1) the public system dependency scale (p<.001), which showed that inpatients required more support from social agencies, 2) the productivity scale, a measure of employment and training (p<.07), which showed that inpatients were less active, 3) the interpersonal isolation from family scale (p<.06), which showed that outpatients had less family contact, and 4) the drug use scale (p<.001), which showed that inpatients abused hard and soft drugs more than outpatients did.

A t test analysis was also performed using the scales of the MMPI and the Taylor anxiety scale. Table 1 displays the results of this analysis. As can be seen, those scales with significant or near-significant differences were schizophrenia, hypomania, personality disorder, hypochondriasis, and depression. In addition, the L scale of the MMPI showed a significant difference. In each of these scales the inpatients rated a higher pathology score.

In order to control for possible contamination by response bias, analysis of covariance was performed on each of the MMPI scales and the Taylor scale using the MMPI L scale as the covariate. As can be seen in table 1, in each case the introduction of the L scale increased the difference between the inpatient and outpatient means and materially reduced the probability level.

A similar analysis of covariance was performed on the Denver questionnaire social functioning scales. In this case, no consistent or significant differences were observed following the introduction of the L scale into the equation.

CONCLUSIONS

The process of review for least restrictive setting described above appears to be a valid mechanism for accurate placement in an inpatient setting or an outpatient setting according to psychopathological and sociodemographic differences. Standardized testing suggests real differences in social support systems for inpatients compared with outpatients. Inpatients appear to be in the peculiar situation of being alienated from the greater society and yet dependent on it. Our results show that inpatients, in contrast to outpatients, require more support from public agencies and from their families, are less likely to be employed or in-

volved in vocational training, and are more likely to abuse drugs. In addition, given placement status, these social functioning scales do not appear to be affected by response bias. This probably reflects the inpatients' casual acknowledgment of the use of and need for a protective environment.

At first blush, the differences in pathology measured by the MMPI and the Taylor scale did not show the magnitude of significance expected when inpatients are compared with outpatients. This is consistent with the results of Dohrenwend and Crandell (3), which showed that outpatients scored worse than inpatients in terms of symptom disclosure. After correcting for response bias in our study, however, a shift in magnitude was revealed. The mean difference between inpatients and outpatients was increased in each of the eight MMPI scales as well as the Taylor anxiety scale. These differences became significant at less than the .01 level in five of the nine scales. The shift in magnitude indicates the effects of response bias on test data. We can hypothesize several different explanations for this tendency:

1. Inpatients feel the vulnerability of being sick and wish to please or to respond as if they were healthier than they are so they will be discharged as soon as possible.
2. The disturbed inpatient does not wish to admit or cannot correctly perceive the presence or extent of his or her illness.
3. Inpatients obtain benefit from being placed in a protective environment. Inpatients may respond to test data more like outpatients because they feel safe and comfortable and because their disorder appears less unusual given their new surroundings.

Whatever the cause, it is clear that response bias plays an important role in the power of tests of pathology to discriminate between inpatients and outpatients. We do not support testing for psychopathology as an antecedent to placement without correcting for response bias when interpreting results. Standardized testing for the need for social support systems, however, does not appear to be influenced by response bias. Preplacement evaluation for these needs may be useful for case management by revealing the availability of external resources.

Our results demonstrate that standardized testing before inpatient or outpatient placement may be an unnecessary intrusion into patient and therapist time. When precise criteria are described, a sequence of evaluation by progressively higher trained clinicians succeeds in accurately placing patients in the setting most appropriate to their needs.

CLINICAL AND RESEARCH REPORTS

This section contains 1) new research findings, including preliminary data from pilot studies, either clinical or laboratory; 2) worthwhile replication studies; 3) case reports that describe a truly new syndrome or cast new light on established ones; and 4) case reports that indicate a new therapeutic procedure of potential value or call attention to adverse effects of drugs or previously unreported complications of therapeutic interventions. Program descriptions and literature reviews cannot be printed in this section. Criteria for format are listed in "Information for Contributors" in each issue; papers that do not adhere to these criteria will be returned to the author.

Psychological Manifestations of Nonbacterial Thrombotic Endocarditis

BY THOMAS B. MACKENZIE, M.D., AND MICHAEL K. POPKIN, M.D.

It is well established that bacterial endocarditis may be heralded by an organic mental disorder (1). However, the psychological presentations of nonbacterial thrombotic endocarditis, also known as marantic endocarditis and degenerative verrucal endocarditis, appear to be unreported in the psychiatric literature. This omission may be explained by the fact that nonbacterial thrombotic endocarditis has been thought to be an incidental autopsy finding (2). Recently, however, it has been recognized as a significant cause of morbidity or death (3). Nonbacterial thrombotic endocarditis may be defined as the presence of fibrin-platelet vegetations on one or more uninflamed, nonulcerated valve leaflets (4). It is generally considered to be a hypocoaguable state (5).

We have recently encountered two patients who had an organic mental disorder that was an early feature of nonbacterial thrombotic endocarditis. These patients illustrate the psychopathology and clinical settings that should alert the psychiatrist to the possibility that the disorder might exist. The following case reports support the addition of nonbacterial thrombotic endocarditis to the psychiatrist's differential diagnosis of etiological factors in organic mental disorders.

Case Reports

Case 1. Mr. A was a 74-year-old farmer who was admitted for evaluation of abdominal pain and a 13.6 kg weight loss. Several days before his admission he had noted the onset of left-sided pain and weakness. In the hospital a well-differentiated adenocarcinoma was discovered after a biopsy was performed on a right pleural mass. The site of the primary carcinoma was unknown, although an abdominal computerized tomography suggested fullness in the area of the pancreas. Findings from a cardiac examination were normal. With regard to his neurological deficits, a head computerized tomography was normal and an EEG showed irregular slowing bilaterally. Psychiatric consultation was sought 6 weeks after admission because Mr. A withdrew, had minimal verbalization, and refused to eat, which suggested a depressive disorder. During the psychiatric examination, a severe organic mental disorder manifested by lethargy, inattention, dysmnesia, and dysarthria was evident. His level of consciousness continued to diminish, and the patient died 50 days after admission. An autopsy showed disseminated adenocarcinoma of the pancreas, nonbacterial thrombotic endocarditis on the mitral valve, and cerebral infarcts of varying ages.

Case 2. Ms. B, a 45-year-old housewife with a 1-year history of disseminated ovarian carcinoma previously treated with melphalan and corynebacterium parvum, was admitted for surgical restaging of her tumor. At the time of admission she was alert and understood the reasons for her admission. While in occupational therapy with other oncology patients several hours later, she became amnesic for recent events and was temporally disoriented. Findings from neurologic and cardiac examinations were otherwise normal. The patient seemed unconcerned about her deficits and when informed of the reason for her hospitalization, she asked whether surgery would be postponed until she improved.

Her physicians suspected a dissociative reaction and requested a psychiatric consultation. During the interview Ms. B seemed embarrassed and stated that her "memory had been scared away." A dense anterograde amnesia and a patchy, inconsistent retrograde amnesia were evident. An EEG with nasopharyngeal leads showed mild diffuse slowing; head computerized tomography was normal; and a two-dimensional echocardiogram suggested mitral valve thickening and prolapse. Five days after the onset of amnesia, she became lethargic and nonresponsive to verbal stimuli and developed a right hemiparesis. Ms. B died 11 days after admission. An autopsy showed disseminated ovarian carcinoma, nonbacterial thrombotic endocarditis on the mitral valve, and cerebral infarcts of varying ages.

Discussion

Psychiatric consultation was sought because both patients were thought to be experiencing psychological symptoms reactive to their malignancies. However, the patients were suffering from organic mental disorders. Mr. A had a delirium that steadily progressed over the course of 1 month. In contrast, Ms. B manifested the abrupt onset of an amnestic syndrome. Autopsies showed that both patients had nonbacterial thrombotic endocarditis and secondary cerebral embolization; cerebral metastases were not present. The appearance of focal findings in Mr. A, e.g., hemiparesis, and the abrupt onset in Ms. B favor an embolic rather than a paraneoplastic etiology.

Nonbacterial thrombotic endocarditis is not a rare occurrence. An estimated 10% of cerebral emboli arise from the disorder (6), and the incidence at autopsy may be as high as 1.6% (7). Between 30% and 50% of patients with nonbacterial thrombotic endocarditis show evidence of cerebral embolization, usually within the distribution of the middle cerebral artery (6). The incidence of microemboli may be much higher.

Nonbacterial thrombotic endocarditis is usually found in persons more than 40 years old who are afflicted with a chronic illness (4). As a result, cachexia is seen in more than half of these patients (7). Eighty percent of the cases of nonbacterial thrombotic endocarditis are associated with known or occult carcinoma, most often of the pancreas, colon, and lung (4). In a majority of cases the malignancy is disseminated; however, in a few patients the tumor is operable at the time nonbacterial thrombotic endocarditis becomes clinically manifest. When associated with a malignancy, nonbacterial thrombotic endocarditis is accompanied by thrombophlebitis in 30% of the cases (8). Chronic heart disease of rheumatic or arteriosclerotic origin is the most common associated condition in patients who do not have cancer (9).

It is impossible at present to determine whether specific psychopathology is characteristic of nonbacterial thrombotic endocarditis because case reports of the disorder have been authored by nonpsychiatric physicians; consequently, details of the mental status are unreported. According to one study (10), 30% of the resultant neurological syndromes are without focal neurological signs. Although the onset of symptoms is usually abrupt, the evolution is subacute and unabating when microemboli are present. A clinical picture of delirium is typical. However, as our second case report shows, nonbacterial thrombotic endocarditis may also be present with selective cognitive impairment. The prognosis for nonbacterial thrombotic endocarditis is usually poor; however, if the tumor has not metastasized, surgical treatment may prevent further morbidity.

In the presence of a progressive or apoplectiform onset of an organic mental disorder, what factors should cause the psychiatrist to suspect nonbacterial thrombotic endocarditis? First is the existence of a malignancy in a person more than 40 years old. A stepwise progression of symptoms suggesting embolic etiology should raise the question of the presence of the disorder. Evidence of thrombophlebitis should heighten clinical suspicion. In a small percentage of cases, the appearance of or change in a cardiac murmur may suggest the existence of vegetations. Evidence of peripheral embolization increases the likelihood of nonbacterial thrombotic endocarditis. Once it is considered, echocardiography can be confirmatory. Abnormal coagulation indices, suggestive of a hypercoagulable state, also support the diagnosis. In our patients head computerized tomography did not detect cerebral embolization secondary to the nonbacterial thrombotic endocarditis. However, in both instances the EEG was diffusely abnormal, confirming the diagnosis of an organic mental disorder.

A Preliminary Report on the Prevalence of Domestic Violence Among Psychiatric Inpatients

BY ROBIN D. POST, PH.D., ALLAN B. WILLETT, M.D., RONALD D. FRANKS, M.D., ROBERT M. HOUSE, M.D., SUSAN M. BACK, PH.D., AND MICHAEL P. WEISSBERG, M.D.

Researchers have gathered data suggesting that domestic violence has become a serious problem in our society (1). At the Yale-New Haven Hospital, Rounsaville and Weissman (2) found that battered women constituted a substantial minority of admissions to the emergency room, psychiatric, and surgical services. These authors believed that the nature and extent of the physical abuse experienced by these women might have remained undetected had staff members not been specifically instructed to ask questions about domestic violence. Hilberman and Munson (3) found that half of the women who were referred for psychiatric evaluation by the medical staff of a rural health clinic reported being victims of domestic violence. Stark and associates (4) criticized physicians and mental health workers for failing to recognize evidence of spouse abuse among their patients and failing to intervene appropriately.

As part of a research project on the adult inpatient units of Colorado Psychiatric Hospital, we designed a structured interview to elicit information about patients' histories of physical aggression. The project simultaneously served teaching, research, and clinical purposes. Our research objectives were to determine the prevalence of domestic violence in a population of psychiatric inpatients and to discover how the personality characteristics and life experiences of victims and of perpetrators of domestic violence differed from each other and from patients without a history of domestic violence. Our clinical objective was to ensure that staff routinely question all patients about domestic violence. Our training objective was to help therapists and other hospital staff to recognize patients with problems of domestic violence and provide effective treatment.

Method

All patients admitted to the two adult inpatient units of Colorado Psychiatric Hospital between August and mid December 1979 were asked to give informed consent and participate in the interview except those patients who remained too disorganized to provide a reliable history or too agitated to handle a one-hour interview. Four research interviewers gave the structured standardized interview, which included questions about incidents of spouse battering and other acts of violence. The interviewers focused on the nature of the violence, the patient's role as victim or perpetrator, the injuries sustained, and the medical and legal consequences of each incident. We will report on spouse battering only.

We defined battering as "significant physical harm inflicted by a partner including slapping, kicking, punching, biting, or attacking with a weapon." We devised 3 categories for the first 60 patient interviews: 1) batterers, 2) victims of battering, and 3) patients who reported no history of spouse battering. A clinical psychologist and a psychiatrist, each having more than 7 years of clinical experience, classified the patients. These classifications yielded initial reliability levels of 85% agreement for batterers and 90% agreement for victims. Those cases where ratings differed were resolved by discussion between raters.

Results

The preliminary results of the 60 interviews (38 women, 22 men) indicated that 29 of the patients (48%) had a history of battering within an intimate relationship. Fifty percent of the female patients (N=19) revealed that they had been battered, while 21% of the female patients (N=8) reported that they had battered their partners. In contrast, 3 male patients (14%) reported being battered, while 6 male patients (27%) had battered their partners. Six women and 1 man (12%) stated they had been both victims and perpetrators of spouse abuse. Of these 7 patients, 1 was clearly a batterer and was beaten by her partner only in self-defense, 1 engaged in battering to protect himself, and 4 alternated as victims or perpetrators in different battering episodes. In the case of the seventh patient, mutual provocation seemed to occur regularly and the partners battered each other. The average age of both the battered patients and the nonbattered patients was 33.7 years, compared with the batterers' average age of 39.0 years. These averages did not differ statistically. Both groups of patients averaged 12½ years of school attendance.

Seventeen of the battered patients (77%) had experienced several abusive episodes. Six victims (27%)

called the police and 8 victims (36%) sought medical attention for their injuries at least once. The victims reported a variety of injuries; the most common were facial injuries, black eyes, bloody noses, split lips, and contusions.

Few of the batterers reported that they had inflicted injuries; only 2 batterers (14%) stated that their victims had sought medical attention. While the batterers may have engaged in milder abuse than that experienced by the battered patients, the data may also reflect a tendency on the part of the batterers to minimize the damage they inflicted. Six of the batterers (43%) reported several abusive episodes. Six of the batterers (43%) also stated that the police had been called.

Discussion

Based on these patient interviews, spouse battering emerged as a major problem in our inpatient psychiatric population. Nearly half of the patients interviewed had been involved in violent episodes with partners and exactly half of the women said they had been battered by partners. As other researchers (5, 6) have previously reported, women appear to have been battered far more frequently than men.

In an earlier study using retrospective data from patient charts ("A Comparison of Battered and Non-Battered Female Psychiatric Patients," to be presented at the American Psychological Association annual meeting, Sept. 1–5, 1980) Back and associates found that therapists had noted a history of spouse abuse for 25% of the female patients sampled. At that time therapists had not been specifically instructed to ask patients about domestic violence. When our interviewers asked direct questions about domestic violence the estimated prevalence of battering among women doubled. This finding supports Rounsaville and Weissman's contention (2) that patients do not readily volunteer information about the violence they have experienced. Our technique of asking patients direct questions about violence in their lives proved highly effective. We were impressed, as were Rounsaville and Weissman (2), with the patients' willingness to talk about problems of spouse abuse. The reported prevalence of batterers in our sample may be an underestimate because of the exclusion of patients who were significantly agitated and/or disorganized. Taintor (7) has suggested that an increased risk of assaultive acts is associated with increasing severity of psychiatric symptoms. It seems that avoidance of knowledge about spouse abuse in psychiatric screening has been more a function of the interviewer's failure to ask about it than the patient's reluctance to talk about such problems.

This research experience has led us to establish two priorities for training in our institution. One priority is to teach therapists to talk effectively with patients about violent experiences. The other is to incorporate questions about domestic violence into psychiatric screening interviews to ensure that patients have the opportunity to reveal their concerns about violence in their lives.

Correlation of Cerebrospinal Fluid Lactate with Age

BY JEROME YESAVAGE, M.D., AND PHILIP A. BERGER, M.D.

Some investigators have suggested that part of the intellectual decline that accompanies aging is due to impaired metabolism of glucose, which in turn results in reduced production of energy-rich compounds that support neuronal function (1, 2). Cerebrospinal fluid lactate levels may provide a measure of cerebral glucose metabolism.

Lactate is mainly derived from glycolysis and removed by oxidative respiration. Increased CSF lactate concentration, therefore, may be due to increased glycolysis, decreased respiration, or both. Lactate crosses the blood-brain barrier slowly, and although it has been shown in animals that lactate concentrations in brain correlate closely with those in CSF, neither brain nor CSF lactate concentrations correlate with sagittal blood lactate (3). Furthermore, it has been shown that lactate concentrations in lumbar and cisternal CSF are correlated even when absolute values are abnormal (4).

Elevated CSF lactate levels are a nonspecific marker of cerebral pathology that may also reflect impaired glucolytic metabolism. Abnormal CSF lactate concentrations have been found in a number of neurological diseases; cerebrovascular accident, meningitis, encephalitis, and intracranial hemorrhage have been associated with CSF levels of lactate two to three times normal concentrations (5). In addition, studies of patients with Alzheimer's disease, a common presenile dementia, have linked elevated lactate concentrations (1.72 mEq/liter) and increased lactate to pyruvate ratios with decreased neurotransmitter turnover and impaired intellectual function (6). However, one other study (5) of a population of patients with a wide range of disease showed that CSF lactate correlated with CSF glucose and that both levels varied with age up to age 50, at which time both levels plateaued. Unfortunately, this study of 177 samples of CSF glucose and lactate included 38 samples with abnormally high values for CSF glucose. Production of lactate can be stimulated in the setting of normal oxidative metabolism by glucose infusions, resulting in high serum and CSF levels of glucose. To our knowledge there have been no studies of CSF lactate in a wide age range of patients with normal fasting blood sugars and without neurological or medical disease. Therefore, the following study was undertaken to examine the CSF lactate levels in normal patients.

Method

The population studied included 41 volunteers with a wide age range (mean age, 45.9; range, 22–70) who were engaged in research on cognitive function and in studies designed to provide normative data for spinal fluid studies. All volunteers were men functioning in the community in similar socioeconomic settings. All could perform detailed cognitive testing involving complex instructions, and none had acute or chronic serious medical or psychiatric illnesses. Unfortunately, because the volunteers were involved in different protocols, no uniform cognitive testing was applied to all of them, except for a basic mental status examination that documented orientation and the ability to do serial subtractions and to remember three objects over 5 minutes. Nonetheless, the volunteers passed the same physical examination and laboratory, ECG, and X-ray studies without evidence of serious defects.

Lumbar punctures were performed between 8:00 and 9:00 a.m. while the volunteers were in the lateral decubitus position and before they arose from bed; they had fasted for at least 12 hours.

Lactate concentrations were measured within 24 hours using a modification of the method developed by Marbach and Weil, which employs the oxidation of lactate to pyruvate (7).

Results

Data were analyzed using Spearman rank-order correlations corrected for ties. The volunteers' ages together with CSF lactate concentrations are presented in table 1. We obtained a correlation of .333 between lactate levels and age, which is significant at the .05 level using a two-tailed test. An examination for a correlation between CSF lactate and CSF glucose concentration was performed. The correlation was negative and nonsignificant ($r=-.152$). Glucose levels fell into a narrow range between 60 and 70 mg/100 ml.

Discussion

These results differ from results found in patients with neurological or medical diseases in that no corre-

lation with CSF glucose was found. This may be partially explained by the narrow range of CSF glucose values and the inclusion of patients with high CSF glucose levels in other studies. Such high glucose concentrations may increase lactate concentrations by increased metabolism of glucose to lactate by the Embden-Meyerhof pathway (4). None of our patients had elevated CSF glucose levels; hence, it is less likely that this effect would be seen.

Future studies of CSF lactate should also control for respiratory function. Although our volunteers were without overt pulmonary disease, arterial PO_2 does decrease with age and is associated with increased CSF lactate production (3). However, subjects with moderate overt pulmonary disease have been found to have normal cerebral circulatory function (8). Nonetheless, whether increased CSF lactate concentrations are related to minimal pulmonary changes associated with age or are due to metabolic disease of the brain, such changes noted in an overtly normal population are potentially important.

Interestingly, not all of our aged volunteers had high CSF lactate concentrations. There were 8 individuals over age 50 with lactate concentrations equal to or less than the mean for those under 50. Nevertheless, the correlation of lactate concentrations with age is consistent with the findings in the group with Alzheimer's disease and in the groups with neurological diseases. Further study with sophisticated cognitive testing should now be done to determine if such changes in CSF lactate concentration are associated with subtle intellectual decline due to degenerative processes that have not yet become clinically obvious.

Training in Brief Therapy: A Survey of Psychiatric Residency Programs

BY JOHN F. CLARKIN, PH.D., ALLEN FRANCES, M.D., ZEBULON TAINTOR, M.D., AND MARIE WARBURG, M.D.

Many factors have caused the recent growth of clinical practice and research in brief psychotherapy. The mental health system is increasingly under pressure to limit costs, justify the utilization of services, and provide prompt and readily accessible care (1). Studies of the outcome of brief therapy have revealed promising and surprisingly enduring results (2). The field is also of inherent interest to clinicians, researchers, and teachers. However, the extent and manner in which brief therapy is taught have not yet been investigated.

This paper reports the findings of a survey of psychiatric residency programs conducted in 1978 by the American Association of Directors of Residency Training. The 152 respondents represented 75% of all active, approved residency training programs in psychiatry in the United States. Thirty-two percent were university affiliated and 30% were university based. A majority of programs (58%) had an eclectic theoretical orientation, 25% were psychoanalytic, and 16% were distributed across such categories as biological, humanistic, and community.

Findings

Eighty-eight percent of the programs offered a training experience in brief psychotherapy, and 78% required it. Only 22% provided their brief psychotherapy instruction as part of a block rotation specifically geared to training in brief therapy. Fifty-two percent had one service that was specifically organized to teach and deliver brief psychotherapy. Sixty-three percent of the training directors predicted that their current emphasis on brief psychotherapy would continue for the next 5 years, while 36% expected growth and only 1% believed that there would be less emphasis on brief psychotherapy.

The training programs that provided formal training in brief psychotherapy varied in their teaching methods. Supervised clinical experience was most prominent (74%), with moderate emphasis on seminars (64%) and supervised reading (60%), and little emphasis on research (10%). The supervised clinical experience usually involved more than 5 patients (60%) or from 3 to 5 patients (29%). The patients spanned a wide range including adults (97%), adolescents (93%), children (76%), families (89%), and couples (88%). The number of sessions for the brief psychotherapy usually ranged from 6 to 12 (71%), with a small percentage consisting of 12 to 30 sessions (19%) or less than 6 sessions (10%). The majority of the programs (57%) had from 2 to 3 brief therapy supervisors. Twenty-three percent had 4 or more supervisors. The supervisors often used video tapes (69%) as teaching instruments and 74% had a follow-up of the patients after the brief psychotherapy.

We inquired about instruction in several different types of brief psychotherapy. The most frequently taught models were: problem solving and anxiety suppressing (79%), crisis intervention (69%), focal or dynamic (58%), and brief family therapy (60%). Only 37% of the institutions taught brief behavior therapy. When asked which model their program taught best, 38% of the training directors selected focal therapy, 23% selected problem solving, 21% crisis intervention, 10% brief behavior therapy, and only 6% brief family therapy.

Discussion

Investigating and documenting the current practices of residency training programs in teaching brief therapy may be helpful in several ways. Data from the survey and from polling training directors about their plans will help to resolve the controversy over what should constitute the essential core of a psychiatric residency. The survey method tabulates data on national practices of training programs and allows each program to determine how it compares with the empirically derived norms. Trends in training can also be determined by comparing the results of surveys performed at regular intervals. Data that document training methods can help to correct misconceptions about program content and can correct the impression that psychiatrists do not learn how to conduct treatment during their residencies.

There are, of course, several limitations to the survey method. The quality of the data depends on the accuracy and thoroughness of the individual responses to the inquiry. It may be difficult to capture in questionnaire format a realistic reflection of the quality, spirit, and effectiveness of the training reported. Survey data describing one portion of a program can be misinterpreted if not seen in the context of the total program.

Our survey suggested that a large majority of residency directors consider training in brief therapy an

essential part of their programs. A majority assume that the current emphasis will continue for at least the next 5 years, while a considerable number predict growing emphasis in the future. We suspect that brief psychotherapy training is expanding, although there are no previous data for comparison. Such growth would reflect increased recognition of its efficacy, the need to adapt long-term psychotherapy to forms that allow for treatment of more patients, and problems of reimbursement. The amount of training in brief psychotherapy already provided indicates the recognition it has achieved, even though this modality is not now specifically included in the *Essentials of Accredited Residencies* (3). The core curriculum requires experience in "individual psychotherapy (including some experience in long-term therapy) . . . crisis intervention . . ." but does not mention brief psychotherapy.

There is an interesting disparity in the current teaching of the various models of brief therapy. Although problem-solving and crisis models are most frequently taught, the training directors more often believe that the focal dynamic model is the one they teach best, perhaps because focal therapy has the best established theory, widest literature, and most definite technical guidelines. Problem-solving brief therapy and crisis interventions are less tied to theory, place greater emphasis on flexibility and resourcefulness, and may be inherently more difficult to teach. As brief therapy matures, the different models will probably become more clearly differentiated from each other, and their instruction will become more systematic, comprehensive, specific, and comparative.

The current organizational practice in the majority of programs is to mix brief therapy training with other training experiences rather than to concentrate it in one block of time. However, half of the programs we surveyed had a specific service to teach and perform evaluations and brief treatment. As more data become available, it should be possible to assess the advantages and disadvantages of using block rotations and specialized services in training residents in brief psychotherapy.

Cerebrospinal Fluid Cortisol Levels in Depression and Schizophrenia

BY DAVID C. JIMERSON, M.D., ROBERT M. POST, M.D., DANIEL P. VAN KAMMEN, M.D., PH.D., JAY S. SKYLER, M.D., GERALD L. BROWN, M.D., AND WILLIAM E. BUNNEY, JR., M.D.

A number of studies suggest that some patients with major depressive illness have a relatively specific abnormality in glucocorticosteroid hemeostasis. Urinary excretion of both 17-hydroxycorticosteroid and free cortisol is moderately elevated in depressed patients in comparison to controls. Plasma cortisol levels are also frequently elevated in depression, especially in the late afternoon and evening, when these patients fail to show the expected circadian decline in cortisol (1). When compared with schizophrenic patients and controls, depressed patients show an early escape from suppression of plasma cortisol following dexamethasone administration (2). The corticosteroid defect appears to be state-dependent, with return to normal responses following symptom remission; however, the altered response may characterize a biologically and clinically distinct subtype of depressive illness (3). The results of one study (2), which are in apparent agreement with urinary and plasma data, showed that depressed patients had elevated levels of cortisol in lumbar CSF (11.4 ng/ml) compared with schizophrenic patients (3.9 ng/ml). In our preliminary study reported here, we did not observe group differences in CSF cortisol levels among patients with depression, schizophrenia, and personality disorder.

Method

To compare the cortisol levels in the CSF of patients with depression, schizophrenia, and personality dis-

orders, lumbar punctures were performed in conjunction with amine metabolite studies on 28 moderately to severely ill hospitalized patients who were diagnosed according to *DSM-III* research criteria. The mean age for the 3 men and 5 women patients selected with endogenous major depressive illness (2 unipolar and 6 bipolar) was 38 years; the mean duration of illness since their first hospitalization was 6.9 years; and the average previous psychiatric hospitalizations per patient was 2.4. The 14 schizophrenic patients, 7 men and 7 women, included 3 patients with schizoaffective illness. The mean age for this group was 26 years, the previous psychiatric hospitalizations per patient was 2.8, with a mean duration of illness of 6.3 years; and their mean score at the time of admission on the Phillips Scale for prognosis of their schizophrenia was 16.3.

A comparison group consisted of 6 men patients (mean age, 23 years) with severe personality disorder but free of major affective illness or alcoholism; they were hospitalized at the National Naval Medical Center, Bethesda, Md. All patients gave informed consent, had been medication free for 2 weeks before the study, and followed a research diet with restricted monoamines. Lumbar punctures were performed at 8:00 a.m. following 9 hours of bed rest and an overnight fast. One-half-milliliter samples of CSF were frozen at −20°C until assayed by radioimmunoassay (4).

Results

The CSF cortisol concentrations (mean±SEM) were not different for patients with depression (16±3 ng/ml, N=8), schizophrenia (20±2 ng/ml, N=14), or personality disorder (21±1 ng/ml, N=6) (F=1.3, n.s., analysis of variance). CSF cortisol values were not related to global nurses' ratings of depression or anxiety in the depressed patients or to psychosis ratings in the schizophrenic patients. Cortisol values tended to be higher in the 3 schizoaffective patients (26±4 ng/ml) than in the 11 other schizophrenic patients (18±2 ng/ml, n.s.). Cortisol values by radioimmunoassay in our patients were somewhat higher than previously published values for normal controls using fluorimetric (5) or competitive protein-binding methods (6).

Discussion

Our observation of similar CSF cortisol levels in depressed patients and neurological controls is consistent with a previous report (7). Values for depressed patients were lower than for controls in a smaller study (8). The relative increase in CSF cortisol in depressed patients reported by Carroll (2) may have been influenced by the administration of 2 mg of dexamethasone 3 days before the lumbar puncture because dexamethasone has a relatively long biological half-life of 36–72 hours (9). Thus, the differences in CSF cortisol levels in that report may in part reflect a prolonged manifestation of the differential response to dexamethasone observed in depressed and schizophrenic patients. Patient characteristics, such as chronicity or severity of illness, could also contribute to differing results. Differences in CSF cortisol concentrations between drug-free depressed patients and other groups might be most apparent in lumbar puncture samples taken in the evening, when the differences in plasma cortisol are most marked. Our observation of similar CSF cortisol levels in schizophrenic patients and controls is in agreement with previous data (5). The tendency toward higher CSF cortisol values in 3 schizoaffective patients suggests the importance of carefully discriminating such patients from other diagnostic groups in future studies of this system. Lerner and coworkers, in work now in preparation, have found similar CSF cortisol levels in depressed patients, schizophrenic patients, and healthy volunteers.

Demonstration of differing levels of cortisol in the CNS of psychiatric patients would be of interest in view of the possibility that brain corticosteroid receptors, in areas such as hippocampus or parietal cortex (10), could be involved in the regulation of cognitive and emotional behavior. Because free cortisol appears to cross the blood-CSF barrier relatively freely (5), future CSF studies should include simultaneous plasma cortisol measurement. The data in this preliminary sample warrant a more extensive study to compare the CSF cortisol levels in depressed and schizophrenic patients with those of a control group of healthy volunteers.

Differentiating Mania from Schizophrenia by the TRH Test

BY IRL EXTEIN, M.D., A.L.C. POTTASH, M.D., MARK S. GOLD, M.D., AND DAVID M. MARTIN, M.A.

Differentiating mania from schizophrenic psychosis has important implications for treatment and has aroused much controversy in recent years (1). Recognition of the specific efficacy of lithium and neuroleptics in the acute and prophylactic treatment of bipolar affective disorder (2) and schizophrenia (3) respectively has resulted in appropriately increased emphasis on distinguishing these two disorders accurately. Despite an impressive body of genetic, biological, clinical, and pharmacological response data supporting the concept of bipolar affective disorder and schizophrenia as distinct entities (1), differentiating mania from schizophrenia in the acute clinical situation can be difficult in many cases. Patients with classic bipolar disorder can in the manic state develop paranoia and Schneiderian first-rank symptoms that are thought to be diagnostic of schizophrenia (4). Similarly, patients with schizophrenic disorder can in the acutely psychotic state manifest hyperactivity, irritability, and grandiosity suggestive of a manic state.

We report here that a biological marker may help distinguish mania from schizophrenia. The magnitude of the release of thyroid-stimulating hormone (TSH) from the pituitary after infusion of thyrotropin-releasing hormone (TRH) can help distinguish unipolar from bipolar depression (5). We report here that manic patients showed a decreased TSH response to TRH compared with psychotic schizophrenic patients. The TSH response to TRH of patients with schizophrenic psychosis was not distinguishable from that of the control patients by the TRH test.

Method

We included in this study five consecutively admitted patients who met Research Diagnostic Criteria (RDC) (6) for mania, five consecutively admitted patients who met RDC for schizophrenia, and a control group of five consecutively admitted patients with the primary diagnosis of personality disorder. The schizophrenic patients were diagnosed as undifferentiated subtype by RDC, and all were actively psychotic. Age and sex distributions for each group of patients were similar. Patients with clinical evidence of thyroid disease were excluded from the study. T_4, T_3-uptake, and TSH levels were determined before the TRH infusion; they were within normal limits for all patients. All patients were free of medications, except flurazepam, for at least 1 week before the TRH infusion. Medication histories of the patients revealed that in the 2 months before the TRH infusion, one of the manic patients, one of the schizophrenic patients, and none of the control patients received neuroleptics. During this time none of the patients received lithium or antidepressants.

An indwelling venous catheter was placed in patients who were at bedrest at 8:30 a.m. after an overnight fast. At 9:00 a.m. 500 μg of synthetic TRH was then administered over 30 seconds through the catheter. Before and 15, 30, 60, and 90 minutes after TRH administration, small samples of blood were obtained for measurement of serum TSH in duplicate by radioimmunoassay (5). The maximum TSH response, or delta TSH, was determined for each patient by subtracting the baseline TSH level from the peak TSH level after TRH administration.

Results

There were no significant differences between patient groups in baseline T_4, T_3-uptake, or TSH levels. The mean serum TSH concentrations for each group before and 15, 30, 60, and 90 minutes after TRH infusion are given in table 1. Within each patient group the mean TSH level at 30 minutes was significantly higher ($p<.01$) than the mean baseline TSH level. There were no delayed peaks. TSH values peaked at 15 or 30 minutes for all patients, except for one schizophrenic patient who peaked at 60 minutes. The TSH response in our control patients was in the same range as reported for normal subjects (7). There were no significant differences between the mean TSH levels for control and schizophrenic patients at any of the time points. The mean TSH levels in manic patients 15, 30, 60, and 90 minutes after TRH infusion were significantly decreased ($p<.05$) compared with control patients at the same time points; at 30 minutes they were significantly decreased ($p<.05$) compared to schizophrenic patients. The mean delta TSH levels in the manic patients was significantly lower than the mean delta TSH levels in the control group and in the schizophrenic patients (see table 1). The mean delta TSH levels in control and schizophrenic patients were not significantly different.

TABLE 1
Serum TSH Levels in Control, Schizophrenic, and Manic Subjects After Infusion of 500 μg of TRH

	Serum TSH Levels (μIU/ml)					
	Control Group (N=5)		Schizophrenic Group (N=5)		Manic Group (N=5)	
Minutes After Infusion	Mean	SE	Mean	SE	Mean	SE
0	2.9	0.4	2.5	0.7	2.3	0.1
15	11.4	1.1	10.1	1.9	6.3	0.9[a]
30	12.9	1.6	11.6	1.4	6.8	1.4[a, b]
60	11.3	1.5	9.4	1.6	5.5	0.8[a]
90	10.3	1.5	6.9	1.2	4.2	0.7[a]
Δ[c]	10.0	1.3	9.3	0.7	4.8	1.1[d]

[a]Significantly different from control patients ($p<.05$, two-tailed t test).
[b]Significantly different from schizophrenic patients ($p<.05$, two-tailed t test).
[c]Determined for each patient by subtracting baseline from peak TSH level after TRH infusion.
[d]Significantly different from control and schizophrenic patients ($p<.02$ and $p<.01$ respectively, two-tailed t test).

Discussion

The results demonstrate a decreased TSH response to TRH in manic patients but not in schizophrenic patients, which is not explainable by differences in baseline thyroid function. This finding is consistent with previous reports of nonsignificant decreases in TSH response to TRH in mania (7). This finding may have practical application in diagnosis and treatment planning, as well as contribute to the understanding of the biological substrate of the two disorders.

The finding demonstrates agreement between clinical diagnosis using reliable and strict diagnostic criteria (RDC) and the magnitude of the TSH response to TRH. This agreement suggests that whenever mania is difficult to distinguish clinically from schizophrenia, the results of the TRH test may help solidify the physician's clinical impression and help determine the choice of treatment. Further research is needed to determine whether the results of the TRH test predict outcome or response to lithium versus neuroleptics in manic, schizoaffective, and schizophrenic states. There has been much interest during recent years in the response to lithium of subgroups of schizophrenic patients (1). Of particular interest may be the pharmacological response of patients whose TRH test results are not consistent with clinical diagnosis, e.g., lithium response in schizophrenic patients with a blunted TSH response.

The release of TSH from the anterior pituitary is mediated by the hypothalamic tripeptide TRH (8). Norepinephrine and dopamine stimulate and serotonin inhibits TRH release (9). Our findings are consistent with the hypothesis that mania is characterized by increased central noradrenergic and possibly dopaminergic transmission. This would lead to increased TRH release and subsequent homeostatic adjustment of the pituitary TRH receptors to become less sensitive or "down-regulate." The TSH response to TRH has been shown to be decreased in unipolar depression (5, 10). An understanding of why unipolar depression and mania manifest similar TRH test abnormalities requires further study. Because there is some evidence that TRH itself has antidepressant effects (10), it is possible that alteration in TRH release is not just an index of changes in brain monoamines but is etiologically related to affective illness.

Catatonia in a Patient with Subdural Hematomas

BY SCOTT W. WOODS, M.D.

When Kraepelin (1) classified catatonia as a subset of dementia praecox, he emphasized that catatonic behavior occurred in many other clinical settings. Nevertheless, reports of catatonia in association with nonschizophrenic illnesses have been overlooked until recently. Gelenberg (2) defined catatonia as a syndrome and referred to catatonic patients who were diagnosed as having affective disorders, neurotic and situational disturbances, and approximately 40 organic conditions. I will describe a case in which transient catatonic signs developed in a patient with bilateral chronic subdural hematomas and presumed Wernicke's encephalopathy.

Case Report

We admitted Mr. A, a 58-year-old unemployed, alcoholic man, to our psychiatric inpatient service for evaluation of his bradykinetic state with organic and catatonic characteristics.

Six days before he was admitted, Mr. A came to the emergency room complaining of a fever and cough that had lasted 3 days and an inability to dress himself during the preceding week. His physical examination was normal, and the emergency room physician diagnosed a viral syndrome. Mr. A refused to leave the hospital after dismissal and was arrested for loitering.

In jail Mr. A sat in one position for long periods, spoke only when spoken to, and was incontinent of urine. The police returned Mr. A to the emergency room because he seemed unable to take care of himself. He was disoriented and remained slow in speech and action. When examining Mr. A, a neurologic consultant noted waxy posturing. Mr. A's limited lateral gaze improved after the emergency room physician had administered thiamine. Mr. A's gait was wide-based and short-stepped. He reported a similar episode that had been diagnosed as "hallucinations," but denied current hallucinations. Review of Mr. A's records indicated that alcohol-related psychoses with hallucinations had precipitated two previous psychiatric hospitalizations. No mention was made of prior catatonia. Mr. A had no family history of psychosis or alcoholism.

His medical history included alcoholism, adult-onset diabetes mellitus, diverticulitis, and hemorrhoids. He took no medicines, was allergic to aspirin, smoked one pack of cigarettes per day, and said he had not drunk any alcoholic beverages for at least 6 days. He had sustained a head laceration with possible loss of consciousness 2 months before admission. A retired Air Force master sergeant, he had been unable to work for the last 5 years, apparently because of alcoholism. He had been sleeping in laundromats for several weeks before coming to the hospital.

I first examined Mr. A two days after his admission. He had deteriorated markedly and was completely incontinent of urine and unable to walk. A mental status exam revealed that Mr. A was alert but oriented only to person. He sat quite still in a wheelchair. He could not repeat any of three words he was asked to remember after a 5-minute time lapse. When pressed for the words, he would touch my knee and proclaim, "You just heard them." He was mute for several periods of 3–5 minutes and engaged in no spontaneous speech. Mr. A answered questions slowly in short single sentences, sometimes appropriately. Some of his replies consisted of changed unintelligible words. I documented no delusions or hallucinations. Mr. A's affect was flat, his face mask-like, and his motor behavior markedly bradykinetic. He did not move the left side of his body spontaneously.

Mr. A's vital signs were normal. He had several well-healed scars on his scalp and a benign systolic murmur. His visual fields were intact to confrontation, although acuity could not be tested. His pupils were equal in size and briskly reactive. Mr. A exhibited complete loss of upward, downward, and intortive voluntary gaze and partial loss of lateral gaze despite full lateral conjugate eye deviation on doll's eyes maneuver. He would not open his mouth. I noted severe generalized muscular rigidity and some spasticity but no catalepsy. Stereognosis and graphesthesia were decreased on his left side. Although I could not test Mr. A's coordination, his deep tendon reflexes were brisk and symmetrical, except for absent ankle jerks. His plantar reflexes were extensor bilaterally. Mr. A stood with difficulty, leaned backward, and appeared not to know how to walk. His snout, root, suck, grasp, palmomental, and jaw jerk reflexes were present.

Laboratory test results revealed a mild macrocytic anemia but were otherwise unremarkable. However, CT scan disclosed subdural hematomas in Mr. A's right parietotemporal region and in his left occipital region. Mr. A underwent evacuation of the right hematoma with gradual resolution of his bradykinesia, incontinence, left-right asymmetries, ophthalmoplegia, hypertonicity, left Babinski sign, and most of his frontal release signs. He still walked with short steps on a wide base. He was oriented to name and time but thought he was in another California city and confabulated on occasion. He spoke at length in a tangential fashion, with normal affect. From the 8th to the 10th postoperative day I observed that Mr. A again demonstrated cataleptic behavior.

Discussion

To my knowledge, this is the first report of subdural hematoma associated with catatonic signs occurring in

an individual with relatively unclouded level of consciousness. The minimal criteria for recognizing the catatonic syndrome have not been adequately determined (3); however, Mr. A's catalepsy, mutism, and stupor seem sufficient (4). In one catatonic patient a subdural hematoma was accompanied by a depressed skull fracture and a semicomatose state (5).

Allen and associates (6) discovered subdural hematomas in 8% of 3,100 consecutive autopsies of state mental hospital patients. Formerly, invasive procedures such as cerebral angiography or exploratory craniotomy may have dissuaded psychiatrists from pursuing the possibility of the presence of subdural hematoma. With the development of brain scanning and of computerized tomography, subdural hematomas may become a more commonly recognized cause of catatonia.

Desipramine: Cardiovascular Effects and Plasma Levels

BY MATTHEW V. RUDORFER, M.D., AND ROBERT C. YOUNG, M.D.

The tricyclic antidepressants can produce symptoms of cardiovascular toxicity such as disturbance of cardiac rate and rhythm, prolonged conduction, decreased myocardial function, and hypotension. These effects have been demonstrated most clearly in cases of tricyclic overdose in humans and in animal studies.

Desipramine has been subjected to little direct clinical study (1) except for an occasional report of overdose (2) or as the major demethylated metabolite of imipramine. The purpose of this study is to quantitate the changes in several cardiovascular parameters by examining a group of clinic patients without heart disease who were being treated with desipramine and to investigate the association between these changes and steady-state plasma levels.

Method

We selected 14 outpatients aged 22 to 41 years old (mean, 30 years), who were free of medical illness and had not been treated with psychotropic medications for 4 weeks. Informed consent was given after the procedures involved in this study were explained. A pretreatment ECG was obtained, together with measures of blood pressure and pulse taken while the patient was sitting and immediately after the patient stood. Desipramine was taken in a single bedtime dose beginning with 50 mg. The dose was increased by 50-mg increments every 3 days until the patient was receiving 150 mg/day of desipramine h.s. Compliance was monitored by pill count. Repeat ECG, pulse, and blood pressure parameters were obtained after 21 days. On days 20 and 21 venous blood samples were collected 10–14 hours after the bedtime dose using heparinized evacuated tubes. Venoject (Kimble-Terumo) tubes were used because they yield reliable determinations that are not suppressed compared with those determinations made from all-glass collection systems (3).

Plasma desipramine levels were determined by gas chromatography–mass spectrometry using the method of Biggs and associates (4), with trifluoracetylimidazole as the derivatizing reagent. Samples were run in duplicate, and paired determinations agreed within 5%. Plasma levels on the 2 days were averaged; the coefficients of variation were within 14%.

Data were analyzed using Student's t test and Pearson's product-moment correlation coefficient. All probabilities are two-tailed.

Results

The mean (±SE) steady-state desipramine level was 201±34 ng/ml; the highest value was 407 ng/ml. The therapeutic range for plasma desipramine levels, although not well studied, is believed to be 100–300 ng/ml (5). Before treatment no ECG abnormalities were noted.

Desipramine treatment resulted in statistically significant increases in PR and QRS intervals, as noted in table 1, but not in the corrected QT (QTc) interval.

TABLE 1
Effect of Desipramine on ECG Findings[a] and Blood Pressure Measurements[a] of 14 Physically Healthy Patients

Measurement	Before Drug Treatment	During Drug Treatment	Change	Significance[b]
ECG rate (beats/minute)	79	94	+15	p<.01
PR interval (milliseconds)	146	158	+12	p<.05
QRS interval (milliseconds)	69	76	+7	p<.05
QTc interval (milliseconds)	402	413	+11	n.s.
Systolic blood pressure, sitting (mm Hg)	120	109	−11	p<.02
Systolic blood pressure, standing (mm Hg)	112	103	−9	p<.02
Systolic positional difference	8	6	−2	n.s.
Diastolic blood pressure, sitting (mm Hg)	80	76	−4	n.s.
Diastolic blood pressure, standing (mm Hg)	79	75	−4	n.s.
Diastolic positional difference	1	1	0	n.s.

[a]Values are expressed as means.
[b]Paired t tests were used.

The ECG interval durations generally remained within normal limits, however. One PR interval was as long as 200 milliseconds, but none exceeded this length. One QRS interval exceeded 100 milliseconds by 13 milliseconds; this was associated with a plasma level of 360 ng/ml. Changes in the PR interval were significantly correlated with pretreatment values ($r=-.60$; $p<.05$); changes in the QRS and QTc intervals were not significantly correlated ($r=.40$ and $-.10$, respectively).

There was a significant correlation between plasma desipramine levels and changes in PR interval ($r=.53$; $p<.05$). Although the correlation between plasma desipramine levels and changes in QRS interval ($r=.49$) was not significant, the 7 patients with QRS increases of greater than 5 milliseconds had significantly higher plasma levels (281 ng/ml±36 ng/ml) than those with smaller increases (122 ng/ml±39 ng/ml; $p<.02$). Plasma desipramine levels were not correlated with changes in QTc interval ($r=-.02$).

Desipramine treatment produced statistically significant increases in the ECG rate up to 115 beats/minute. The increase in ECG rate during treatment was correlated with the pretreatment rate ($r=-.53$; $p<.05$). The resting radial pulse of patients increased in both sitting (mean, 76–90; $p<.01$) and standing (mean, 87–104; $p<.01$) positions. The patients did not complain of palpitation. Plasma desipramine levels were not correlated with changes in the ECG rate ($r=.15$).

Desipramine treatment was associated with consistent but small decreases in systolic blood pressure in both the sitting and standing positions. These decreases were correlated with pretreatment values ($r=.84$ and .93, respectively; $p<.001$). Before treatment there was a small drop in systolic blood pressure when patients rose from a sitting position to a standing position ($p<.05$) and during treatment ($p<.02$); the magnitude of this difference did not change significantly. Changes in systolic positional difference were correlated with pretreatment differences ($r=.69$; $p<.01$). Diastolic blood pressure was not significantly altered either by posture or by drug treatment. Changes in diastolic blood pressure during treatment were significantly correlated with pretreatment values sitting ($r=.77$; $p<.01$) but not with pretreatment values standing ($r=.41$). Changes in diastolic positional difference were significantly correlated with pretreatment differences ($r=.88$; $p<.001$). Standing also produced an increase in pulse rate both before and during treatment ($p<.001$); the degree of this increase did not change significantly. The subjects did not have subjective or objective complications of hypotension.

Plasma desipramine levels were significantly correlated with changes in systolic positional difference during treatment ($r=.64$; $p<.05$); these levels were not significantly correlated with changes in systolic blood pressure sitting or standing ($r=.35$ and 0, respectively), with changes in diastolic blood pressure sitting or standing ($r=-.05$ and .21, respectively), or with changes in diastolic positional difference ($r=.27$).

Discussion

These young, physically healthy subjects who were treated with desipramine had consistent prolongation of intracardiac conduction. This finding contrasts with the apparent lack of such an effect detected in similar subjects at therapeutic plasma levels of amitriptyline (6) and nortriptyline (7); to our knowledge these drugs reportedly produce only tachycardia in such subjects. In further contrast, the therapeutic total tricyclic levels of patients being treated with imipramine, the tertiary amine of desipramine, have been reported to produce not only tachycardia but greater degrees of conduction delay (8, 9) and significant postural blood pressure changes (10); however, these patients were older and had preexisting heart disease.

More data comparing the cardiovascular toxicities of individual tricyclics at therapeutic plasma levels in older and in young healthy populations are needed.

Cardiovascular Effects of Nortriptyline in Geriatric Patients

BY KENNETH REED, PH.D., M.D., ROBERT C. SMITH, M.D., PH.D., JOSEPH C. SCHOOLAR, PH.D., M.D., RICHARD HU, M.D., DODDAMANE E. LEELAVATHI, PH.D., EDWARD MANN, M.D., AND LOIS LIPPMAN, R.N.

Concern about the cardiovascular side effects of antidepressant medication may often deter clinicians from prescribing these drugs appropriately for depressed patients with a history of ECG evidence of cardiac disease. Epidemiological studies have suggested that amitriptyline may be associated with sudden death in patients with cardiac disease (1, 2). Vohra and associates (3) and Burrows and associates (4) investigated the effects of antidepressants on intracardiac conduction in clinical and experimental studies and concluded that nortriptyline may be particularly cardiotoxic and that it may have significantly greater effects on several ECG parameters than doxepin. Zeigler and associates (5) reported the development of premature ventricular contractions in a 65-year-old man treated with nortriptyline. However, Freyschuss and associates (6) reported that nortriptyline had very little effect on inducing orthostatic hypotension. Because many geriatric patients suffering from clinical depression will also have evidence of preexisting cardiac disease, psychiatrists may refrain from using antidepressant medication in these patients or may prescribe doses that are too low to obtain maximum therapeutic efficacy. To assess more accurately the clinical importance of cardiac side effects of antidepressant medication in the elderly, we report here the preliminary results from a controlled study we conducted on the effects of standard doses of the tricyclic antidepressant nortriptyline in geriatric and nongeriatric depressed patients.

Method

We selected as our study group 12 geriatric depressed patients who were being treated in the inpatient services of the Texas Research Institute of Mental Sciences or the Texas Kerrville State Hospital. The patients had a mean age of 67.8 years (range, 60–78 years). Three younger depressed patients were also selected; they had a mean age of 25.8 years. After a 1- to 3-week drug-free washout period, each patient was started on a fixed dose of nortriptyline, usually 150 mg/day t.i.d. To determine the effects of nortriptyline on the patient's cardiovascular system a standard ECG recording was made once or twice a week during the patient's drug-free period and then 2 to 4 weeks after the patient started treatment with nortriptyline. Our ECG results were based on an average of 2.6 ECG recordings per patient in the predrug period and 3.9 recordings during regular treatment with nortriptyline. A research nurse using a standard procedure assessed the patient's orthostatic hypotension two or three times a week in the morning before the first dose was administered. Blood pressure was checked twice while the patient was resting in bed and checked twice again within a minute after the patient stood up. Plasma levels of nortriptyline were determined by drawing plasma samples twice a week between 8:00 a.m. and 8:30 a.m., 11 to 12 hours after the previous night's dose had been taken. The assays of nortriptyline were done by a gas liquid chromatographic procedure with a

nitrogen detector; chlorimipramine was used as the internal standard.

Results

Most geriatric patients achieved plasma levels of nortriptyline (mean steady-state plasma levels=90–160 ng/ml) within or slightly above the previously established therapeutic window for nortriptyline (see table 1). At these plasma levels nortriptyline had no clinically significant effects on the ECGs of geriatric patients. The mean (±SD) changes in standard ECGs when the patients were receiving nortriptyline as compared with their ECGs during the predrug washout period were heart rate=3.5±6.6 beats/minute; QT_c=6±29 milliseconds; PR=11±10 milliseconds; QRS=10±11 milliseconds. Although some of the geriatric patients had statistically significant increases in heart rate and QT_c, no patient's mean heart rate increased to levels above 100 beats/minute, i.e., none experienced clinically significant tachycardia, and the maximum increase in mean QT_c was 32 milliseconds. Even when patients who had evidence of clinically significant preexisting cardiac disease were treated with standard doses of nortriptyline (150 mg/day) and had plasma levels up to 180 ng/ml (patients 1 to 6 in table 1), nortriptyline produced no evidence of increased cardiovascular toxicity.

The effects of nortriptyline on decreasing intracardiac conduction were evident in patient 1. She was studied a second time with 24-hour Holter-monitor ECG recordings made weekly during 3 weeks of a drug-free washout period and subsequently during several weeks of treatment with 100 mg/day of nortriptyline. When her plasma nortriptyline levels were 140–180 ng/ml, her ectopic beats decreased from a mean of 42 ectopic beats per 24-hour period during the 3-week baseline period to a mean of 15 ectopic beats per 24-hour period during her third week of treatment with nortriptyline. When she had previously been treated with a higher dose of nortriptyline, 150–200 mg/day, she had plasma levels of 187–250 ng/ml; standard ECGs showed that she had developed signs of first-degree heart block. This subsided when the nor-

triptyline dose was reduced. These quinidine-like effects of nortriptyline are similar to those previously reported (7, 8) for another antidepressant, imipramine.

The degree of orthostatic hypotension produced by nortriptyline did not differ in 5 geriatric and 3 younger patients in whom we made standardized assessments. Orthostatic hypotension results, therefore, were combined across age groups. Nortriptyline did increase the drop in the systolic component or orthostatic hypotension but not in the diastolic component. During the washout period the mean drop in systolic pressure when the patient changed from a lying position to a standing one was 10.3 mm Hg; during the regular treatment with nortriptyline the mean drop was 24.6 mm Hg. Therefore, the effect attributable to nortriptyline was 14.3 mm Hg. This is similar to the reported effect (7, 9) of imipramine on the systolic component of orthostatic hypotension (mean=−15.2 mm Hg). The mean drop in diastolic pressure from lying to standing during the washout period was 1.9 mm Hg, and during treatment with nortriptyline it was 3.8 mm Hg, resulting in a drug effect of 1.9 mm Hg. This is smaller than the drug effect on diastolic orthostatic hypotension reported for imipramine (mean=−12 mm Hg) (7, 9).

Discussion

The cardiovascular effects of nortriptyline in these geriatric patients appear to be different in important respects from previous clinical reports (1, 6). A standard dose of nortriptyline, 150 mg/day, produced blood levels within or slightly above the therapeutic window in most of the geriatric patients. We found nortriptyline at this dose to be safe in regard to cardiovascular toxicity, even in patients with stable, preexisting cardiovascular disease.

It is important to look at the dose, blood levels, and clinical condition of the patient when interpreting the differences between our results and those of other investigators. Vohra and associates (3) and Burrows and associates (4) reported clinically significant effects of nortriptyline on the patients' ECGs. The mean nortriptyline level of their patients, however, was 196 ng/ml, which is well above the therapeutic window; a few of their patients had plasma levels of 300 ng/ml or 400 ng/ml. In the study by Zeigler and associates (5) the patient who developed premature ventricular contractions had a nortriptyline level of 176 ng/ml. In contrast, most of the patients in our study had nortriptyline plasma levels between 90 and 160 ng/ml. The patient who developed first-degree heart block had nortriptyline levels above 187 ng/ml. These comparisons emphasize the importance of considering the patient's blood levels of the antidepressant when making clinically relevant interpretations of the comparative cardiac toxicity of antidepressant drugs.

Although other researchers (1, 2) reported a significantly higher number of sudden deaths due to cardiac conditions in patients treated with amitriptyline, many of the amitriptyline patients they studied were admitted to a hospital with acute conditions. On the other hand, all of our patients with preexisting cardiac disease had relatively stable, nonacute cardiac conditions.

Orthostatic hypotension may be a clinically more important side effect of antidepressants, particularly in geriatric patients. More frequently than other cardiovascular side effects, orthostatic hypotension may occur at antidepressant blood levels necessary for adequate clinical response. Contrary to the results of Freyschuss and associates (6), who reported no decrease in orthostatic blood pressure due to nortriptyline, our results indicate a significant effect of nortriptyline on systolic orthostatic hypotension. This effect is quantitatively similar to that reported by Glassman and associates (9) for imipramine. Although nortriptyline produced less orthostatic hypotension in the diastolic component than imipramine, the clinical significance of the systolic versus diastolic component of orthostatic hypotension is unclear.

Other preliminary data for our study (10) indicate that at these standard doses nortriptyline is an effective antidepressant in geriatric depressed patients. We believe, therefore, that standard doses of nortriptyline, e.g., 100–150 mg/day, may be used safely and effectively in geriatric patients, even for those with stable, preexisting cardiac conditions. Plasma-level monitoring, however, may be more mandatory in geriatric patients in order to quickly identify those patients who may be subject to greater risk of cardiac side effects. These conclusions pertain to the specific tricyclic antidepressant we investigated, nortriptyline, and may not be generalizable to other antidepressant drugs.

Iatrogenic Opiate Addiction: Successful Detoxification with Clonidine

BY DENNIS S. CHARNEY, M.D., AND HERBERT D. KLEBER, M.D.

Recently researchers have documented the effectiveness of the α_2-adrenergic agonist, clonidine, in eliminating objective signs and subjective symptoms of heroin and methadone withdrawal (1–3). These preliminary findings suggest that clonidine enables a faster, less severe detoxification from opiate drugs than gradual methadone reduction. If these observations are confirmed, clonidine will be potentially useful not only in detoxifying heroin and methadone addicts but also in treating patients with iatrogenic addictions resulting from chronic pain syndromes. The following is, to our knowledge, the first report of the use of clonidine to detoxify an iatrogenic opiate addiction secondary to chronic pain.

Case Report

Ms. A, a 51-year-old woman, had a 28-year history of chronic interstitial cystitis. For the past 15 years, Ms. A had been addicted to an oxycodone combination (Percodan), which she had begun to take because of chronic bladder pain. During the last 10 years she had been taking at least 40 tablets per week. Her urologists felt that Ms. A's complaints were excessive and her constant use of narcotics unwarranted. Despite these reservations, her physicians constantly supplied Ms. A with oxycodone prescriptions. During Ms. A's 15-year use of oxycodone both as an inpatient and an outpatient, several attempts to taper the oxycodone failed. Six years before we admitted Ms. A, she had attended once a week psychotherapy sessions for 6 months. Her therapist had described her as a chronically depressed woman with passive-dependent personality features.

In September 1979 Ms. A was referred to our Drug Dependence Unit by her urologist, who was no longer willing to supply oxycodone prescriptions for Ms. A's chronic complaints of bladder pain. In addition to oxycodone, Ms. A was receiving propanolol, 40 mg t.i.d., and hydrochlorothiazide, 50 mg/day, for essential hypertension and chlordiazepoxide hydrochloride, 10 mg t.i.d., for chronic anxiety. We could not definitively ascertain the etiology of Ms. A's pain, but it was clear that psychological issues contributed to it and that Ms. A had become tolerant to the analgesic effects of oxycodone. Considering this tolerance and Ms. A's history of unsuccessful detoxification attempts, we recommended oxycodone detoxification with clonidine.

At admission Ms. A weighed 86.4 kg and her standing blood pressure was 120/80. On the first day of hospitalization Ms. A received her regular doses of oxycodone (1 tablet, 4.5 mg, every 4 hours). However, we decreased her propanolol dose to 40 mg b.i.d. and discontinued her diuretic because of the anticipated synergistic interaction with clonidine in lowering blood pressure. We maintained Ms. A's chlordiazepoxide hydrochloride dose of 10 mg t.i.d. throughout her hospitalization to avoid a benzodiazepine withdrawal syndrome. On day 2 we discontinued oxycodone, and gave a single 40-mg dose of propanolol, and administered clonidine, 0.1 mg at 8 a.m. and 3 p.m., and 0.2 mg at 10 p.m. We continued to administer clonidine until Ms. A was discharged on day 10 (see table 1).

Throughout her hospitalization Ms. A's withdrawal signs and symptoms were assessed by a nurse's abstinence rating scale (2) three times daily. We checked Ms. A's blood pressure, lying and standing, and her pulse immediately before and 1 hour after administering clonidine, except for the first 2 dosages, when we took her blood pressure each hour for 3 hours after administering the clonidine.

Based on the abstinence scale and clinical observation, Ms. A exhibited few signs or symptoms of withdrawal. We observed only mild anorexia (days 3–5) and diarrhea (day 4). On day 2 Ms. A complained of a headache. Since the oxycodone combination contained caffeine, we thought Ms. A's headache might be a symptom of caffeine withdrawal and advised her to increase her coffee intake. This stopped the headaches and they did not recur. Ms. A had a significant fall in standing blood pressure, from 120/80 to 90/60, at the higher doses of clonidine, which are associated with mild postural dizziness and lightheadedness. Ms. A did not complain of pain during hospitalization. At discharge she was asymptomatic, her blood pressure had returned to 120/80, and the only medication she was receiving was a diuretic.

At a 6-month follow-up Ms. A remained free of narcotics and was attending biweekly supportive psychotherapy sessions at the Drug Dependence Unit. Her urologist remarked that he had never seen her so alert and energetic.

Discussion

Although somewhat milder, the abstinence syndrome associated with oxycodone resembles that of

9	.1	0	0	.1

[a]On hospital day 1, the patient received oxycodone, 1 tablet every 4 hours; on hospital day 10, the patient was discharged.

morphine and lasts approximately 7 days (4). In Ms. A clonidine almost completely blocked the emergence of the syndrome, presumably by reducing norepinephrine turnover in the central nervous system (5).

The effective clonidine dose in Ms. A (10 μg/kg per day) resembles doses used in previous studies with heroin and methadone addicts in which doses up to 17 μg/kg per day were used (1–3). We used the three-times-daily dosage schedule because a single dose of clonidine can eliminate the opiate abstinence syndrome for 240–360 minutes (1). Two factors determined the necessary duration of clonidine administration for smooth detoxification: 1) the half-life of the addicting narcotic, which is related to the length and intensity of the untreated abstinence syndrome, and 2) the need for a clonidine taper. Abrupt discontinuation of clonidine causes a withdrawal syndrome (6), but its effects are not severe and patients can withdraw from clonidine with relative ease. Five days of relatively high doses of clonidine and a 3-day taper provided a safe, effective detoxification for Ms. A.

These findings may have several important therapeutic implications. Prescription drug addiction is a common problem for patients complaining of chronic pain (7). Clonidine can be used as a rapid nonnarcotic means of helping these patients to withdraw from narcotic analgesics. Clonidine in conjunction with psychotherapy may enable patients who do not suffer from discernible physical illness but who have psychological difficulties to detoxify and remain drug free. For patients with painful physical disease, periodic clonidine detoxifications may provide more effective analgesia by temporarily reversing the tolerance developed over long-term narcotic use. These patients may not complain of pain during the detoxification because clonidine has been shown to have analgesic properties similar to the effects of morphine in laboratory animals (8, 9).

IN MEMORIAM

Hugh Thompson Carmichael 1898–1980

I met Hugh Carmichael when he spoke to our freshman medical class at the University of Illinois in Chicago; he was then and to the end of his days one whose presence lent a dignity to his surroundings. I next met Hugh Carmichael during my training at the university department of psychiatry. He became my mentor, analyst, colleague, and friend. Those were the halcyon days for many of us at Illinois when, under the direction of our department head Melvin Sabshin, Carmichael was appointed director of undergraduate education in psychiatry. Many of us, infected by his enthusiasm and abiding quest for excellence, became involved with the problems of curriculum design, experimental teaching formats, and evaluation mechanisms. His style of leadership was particularly supportive of new directions; he welcomed and was an instant advocate of creativity in teaching and learning, which he would energetically advance if it fulfilled his standards of excellence (Hugh did not too gladly abide foolishness).

When he came to work for APA after retirement from the University of Illinois, Carmichael continued his interest in education, now with an emphasis on the self-assessment of the members of the American Psychiatric Association, which would hopefully lead to self-improvement and a lifetime of learning. Once again he was able to infect a number of willing workers with the abiding notions of the Carmichael litany, which emphasized excellence as a way of life. Carmichael's emphasis (1–4) on the continuation of the education of psychiatric physicians was one of the important early influences on the continuing education movement.

Carmichael had many other "selves"; in his lifetime he was a general practitioner, a neuroendocrinologist, a neurologist and neuropathologist, a research psychiatrist, and a training and supervising psychoanalyst (Chicago Institute for Psychoanalysis). He held important positions in many major bodies in psychiatry and psychoanalysis, including the vice-presidencies of the American Psychiatric Association and the American Board of Psychiatry and Neurology. From his origin in Peterborough, Ont., Canada, at the turn of the century, his educational and professional travels took him to the Mayo Clinic, Albany Medical College, Worcester State Hospital, and the University of Chicago hospitals and medical school, among other places. His scientific and professional activities in these years ranged from psychophysiologic research to neuropathological investigations.

When he came to Chicago in the 1930s, Hugh Carmichael worked with Grinker at the University of Chicago and began his psychoanalytic training with Terese Benedek, who became his revered mentor and analyst. It was under her guidance that he wrote his first analytic paper, "A Psychoanalytic Study of a Case of Eunuchoidism" (5). For 25 years he was a training and supervising analyst at the Chicago Institute for Psychoanalysis. When he transferred to the University of Illinois in the 1950s, it was to help develop the department of psychiatry at Illinois with Francis Gerty. With his characteristic vigor he here influenced many young psychiatrists to become involved in psychoanalytic psychiatry. It was also at Illinois that he performed the first psychotherapy that was filmed.

A description of Hugh Carmichael would never be complete without telling of his generosities as friend and as physician. Perhaps one of his most important "teaching" activities was to take us into his home, to demonstrate through his interactions with his ever-gracious wife Carolyn and his family how to "do business," as he always said, in a family setting. The atmosphere was always filled with merriment and, more importantly, the sense of acceptance by our leader.

These considerations lead to the final summarization of Hugh Carmichael as the complete teacher—one who through his example of gentility and empathy, his capacity to function as a nurturer of our autonomy, and his capacity to lend content to our ideals helped develop in all those who came under his wings the impetus to achieve. He was, I believe, a fortunate man; he had achieved the ability to stand apart from his students and be filled with joy at their accomplishments. What man could wish for more?

LETTERS TO THE EDITOR

This section contains reactions to Journal *articles, statements of opinion, brief research findings or ideas, short case descriptions, requests for information, etc. Letters should be submitted in duplicate to the Editor, who makes all decisions regarding publication. Letters must be typed double spaced throughout and should not contain more than 500 words and 5 pertinent references. Criticisms of published articles will automatically be sent to the author(s) for response. Letters will be edited for clarity and conformance with* Journal *style. We regret that we cannot inform writers of the disposition of letters or return those which are not printed.*

Defining Drug-Induced Supersensitivity

SIR: In "Neuroleptic-Induced Supersensitivity Psychosis: Clinical and Pharmacologic Characteristics" (January 1980 issue), Guy Chouinard, M.D., M.Sc., and Barry D. Jones, M.D., proposed that patients whose psychosis becomes progressively resistant to neuroleptic therapy and show end-of-dose symptom exacerbation should be considered dopaminergically supersensitive. They compared this supersensitivity with that seen in patients with tardive dyskinesia, relating the former to mesolimbic dopamine receptors and the latter to the striatum. While the description of such patients may be accurate, the use of the term "supersensitive" to describe these symptoms is unwarranted from the data given and may be entirely misleading in terms of neuropharmacologic implications.

Drug-induced supersensitivity refers to an enhanced behavioral or biochemical response to an agent (1). The development of a new symptom complex after drug exposure, as seen with tardive dyskinesia, or the development of symptomatology that is more marked after drug exposure than before therapy are examples of drug-induced supersensitivity. The cases presented by Drs. Chouinard and Jones, however, do not fit these criteria.

The patients described were psychotic when neuroleptic therapy was initiated and became psychotic again as their next dose of depot neuroleptic approached. Eventually their psychoses were no longer controlled by the former doses of medication, so that higher neuroleptic doses were required. When a higher drug dose is needed to achieve the same behavioral effect, we refer to the phenomenon as "tolerance." There is no indication from the report that the psychosis itself progressed, only that the same symptoms tended to recur at doses that had formerly controlled them.

Before maintaining that the patients showed supersensitivity, the authors must demonstrate a clear progression of the psychotic symptom complex itself, perhaps in the form of new hallucinations in patients who never hallucinated before or a significant deterioration in thought disorder compared with premedication psychiatric evaluation. Drs. Chouinard and Jones provided no data to indicate that this progress occurred, so the assertion that these patients showed dopaminergic supersensitivity was premature and unjustified.

I do not dispute the possibility of mesolimbic supersensitivity. Laboratory data on receptor site changes in this system after chronic neuroleptic exposure suggest that, at least in experimental animals, the phenomenon may exist. Rather, I would emphasize the precise pharmacologic restrictions of supersensitivity and stress the importance of an appropriate experimental design to identify it.

CHRISTOPHER G. GOETZ, M.D.
Chicago, Ill.

Drs. Chouinard and Jones Reply

SIR: Dr. Goetz appears to have overlooked an important characteristic of the phenomenon we described—the increased frequency of the reemergence of psychotic symptoms in patients treated chronically with neuroleptics. The courses of our patients' illnesses were different from those one would normally expect in schizophrenia. In our patients relapse occurred immediately and invariably with drug withdrawal or dosage reduction and their symptoms emerged as drug blood levels declined. Before "supersensitivity" developed, the relapse rate averaged once per year. Not only did the frequency of relapse increase markedly, but this kind of relapse differed from that of the true schizophrenic relapse because it could be controlled immediately by increasing the drug dosage. For this reason we chose the term "supersensitivity" to characterize the emergent psychosis. If we were to experimentally demonstrate the emergence of psychotic symptoms not previously present or exacerbation of symptoms by the long-term administration of neuroleptics, we would have to administer neuroleptic drugs to nonpsychotic subjects or deliberately allow exacerbation of symptomatology without appropriate dosage adjustment. Both of these approaches would be unjustifiable from an ethical point of view. We intended our article to draw attention to signs of what we consider to be supersensitivity to the drug's antipsychotic action developing in patients on long-term neuroleptic treatment.

When we speak of "tolerance," we mean "behavioral tolerance" and not "metabolic tolerance" as Dr. Goetz seems to imply. Behavioral tolerance to chronic treatment consists of a return of behavior to pretreatment baselines after significant initial changes, and is related to a neurochemical adjustment at a subcellular level. Behavioral tolerance to neurolep-

tics has been clearly shown to occur in animals (1). In humans behavioral tolerance to sedative action and parkinsonian side effects of neuroleptics is well established. However, tolerance to the therapeutic effect of neuroleptics has not been demonstrated. We first observed this tolerance in a double-blind study examining the therapeutic effect of long-acting injectable neuroleptics (2). Furthermore, metabolic tolerance was ruled out in our patients since their prolactin levels continued to increase with increased doses of neuroleptics.

We drew the analogy between the supersensitivity psychosis and tardive dyskinesia because both are related to long-term neuroleptic administration, follow a similar progressive course, and respond in the same manner to dosage variations. A recent study demonstrated an increase in dopamine binding sites in the mesolimbic regions of postmortem brains of schizophrenic patients that correlated with neuroleptic treatment (3). This finding supports the theory that supersensitivity in the mesolimbic region causes the increased frequency of reemergence of psychotic symptoms.

A Political Implication of Drug-Induced Supersensitivity

SIR: "Neuroleptic-Induced Supersensitivity Psychosis: Clinical and Pharmacologic Characteristics," by Guy Chouinard, M.D., M.Sc., and Barry D. Jones, M.D. (January 1980 issue) will heighten psychiatrists' concern about the adverse effects of these powerful drugs. I would like to point out another unhappy implication of these findings. The abuse of psychiatry for political purposes, e.g., silencing dissenters by removing them to mental hospitals for "treatment" has been well documented (1, 2) and has drawn official condemnation from the World Psychiatric Association. This practice may include the forcible administration of neuroleptics over long periods of time (2). The possibility arises that a psychotic state based on supersensitivity could be induced in a previously nonpsychotic "patient" held in such circumstances. Although this might occur in only a minority of cases, the chances would be increased by severe environmental stress. Subsequent examination by an impartial team investigating alleged abuse might then reveal the presence of psychosis (which did not exist before "treatment") and the investigators might incorrectly conclude that the hospitalization and treatment had been clinically justified.

Cases of alleged political abuse of psychiatry involving involuntary administration of neuroleptics should be investigated as quickly as possible, before the "treatment" itself could cloud the clinical picture. American psychiatrists should continue to confront this important issue in the forum of the World Psychiatric Association and to press for the early investigation of all cases.

In Defense of the JCAH

SIR: I would like to comment on Dr. Daniel B. Schuster's letter to the Editor, "The Burden of Documentation" (May 1980 issue).

The Joint Commission on Accreditation of Hospitals has always enjoyed and promoted a favorable working relationship with the medical community. In the past several years we have made a conscious effort to strengthen that relationship. We believe one of the outcomes has been significant involvement in all aspects of the survey and accreditation programs by members of APA.

Standards of the Joint Commission consistently stress medical responsibility for patient care. Concurrently, they have attempted to appropriately acknowledge the role and responsibilities of nonmedical professionals in the field of mental health. We appreciate Dr. Schuster's concern with the increase in need for documentation. This issue is among many that are receiving close attention as the proposed revisions to the *Consolidated Standards*. They are currently being subjected to extensive review by the mental health field. As in the past, comments from APA members will make an important contribution to the final revision of these *Standards*.

The role of the Joint Commission is to develop quality assessment and quality assurance mechanisms that will assist facilities in creating an appropriate setting for the delivery of optimal, achievable patient care. We seek to accomplish this task through a thoughtful process of education, consultation, and evaluation in cooperation with the field we serve.

JOHN E. AFFELDT, M.D.
President, Joint Commission on Accreditation of Hospitals
Chicago, Ill.

Assessing Mistakes in Psychotherapy

SIR: In "Common Mistakes in Psychotherapy" (December 1979 issue) Peter Buckley, M.B., Ch.B., and associates addressed an area important to all of us involved in the teaching and practice of psychotherapy. However, the authors omitted information essential to the proper evaluation of their contribution. This presumably unintentional omission could reflect a tendency to overgeneralize their findings.

The term "mistake" implies there is a correct or appropriate type of therapy to be administered. What is termed correct or appropriate psychotherapy in any given case of psychotherapy supervision depends on at least three factors: the type or diagnosis of the patient, the type of psychotherapy

being conducted, and the theoretical orientation of the supervisor. I teach psychotherapy on a general inpatient service where we treat severely disturbed patients. Buckley and associates listed "wanting to be liked by the patient" as the most common mistake in psychotherapy. However, on our inpatient service "wanting to be liked by the patient" more frequently indicates that the therapist is building an emotionally positive, trusting, working alliance, the primary requirement for psychotherapy with our patient population. A supervisor of the existential school of psychotherapy who stresses sharing the patient's experience would be more likely to view the "stereotyped 'analytic psychotherapist' stance" as a mistake than would a psychoanalytic supervisor.

Buckley and associates should have noted how certain supervisors commented on certain types of therapy for certain types of patients. If, as seems likely, the information was gathered largely from cases of moderately to well-functioning patients in insight-oriented therapy supervised primarily by psychoanalytically oriented staff members, the authors should so inform the reader. We need to know to what degree the findings are generalizable and not assume that they are so.

The title of the article did not mention that the therapists concerned were residents. Although the body of the article does clearly state the training status of the therapists, it also refers to the possible general applicability of the findings. Again, such general applicability should be demonstrated, not assumed. The title should accurately describe the contents for those readers who will only skim the article. Perhaps "Common Mistakes in Psychoanalytically Oriented Insight Psychotherapy by Psychiatric Residents" would have been better.

I appreciate Dr. Buckley and associates' paper and it is because I agree with the need to better evaluate psychotherapy that I write my comments.

BRUCE W. SCOTTON, M.D.
San Francisco, Calif.

Dr. Buckley and Associates Reply

SIR: Dr. Scotton is incorrect in assuming that our report of common mistakes was based on an a priori theoretical view of correct or appropriate psychotherapy. We based our 56-item questionnaire on elements in psychotherapy that had previously been related to negative effects by researchers (1) as well as on our own clinical experience and not on a particular theoretical ideology.

We also feel that there is some confusion on Dr. Scotton's part between the establishment of a working alliance and the wish on the part of the therapist to be liked by the patient. We do not think that these are equivalent. If the therapist's needs are unconsciously paramount in the treatment, it can hardly be therapeutic for the patient even if he or she likes the therapist. The therapist who wishes to be liked by a severely disturbed patient may ignore aspects of the patient's communication that are discrepant with that wish and hence obviate an effective treatment. We also feel that "assuming a stereotyped analytic psychotherapy stance regardless of the actual treatment situation" is a mistake, no matter what the theoretical orientation of the therapist or the supervisor might be. We believe such rigidity is inimical to effective therapy.

Our group of supervisors were primarily of a classical psychoanalytic persuasion, but the group did include practitioners trained in existential and interpersonal schools of psychoanalysis. We are not convinced that the theoretical beliefs of supervisors are as critically important as Dr. Scotton would suggest, since a number of studies have shown that theoretical distinctions between therapists blur with extensive experience and that experienced therapists, despite differing theoretical orientations, are more alike in technique than inexperienced therapists (2, 3).

We agree with Dr. Scotton that our title was too broad and that we should have indicated that the psychotherapy was being conducted by psychiatric residents.

On New Trends in Psychotherapy

SIR: "Recent Trends in Psychotherapy" (April 1980 issue) by Judd Marmor, M.D., is a lucid, comprehensive psychosocial analysis of the factors involved in the explosion of new psychotherapies.

Dr. Marmor wrote, "It is a romantic notion that inner experiences alone can change and transform external reality . . . . We are responsible for much that happens to us, but the illusion of total responsibility can be destructive to a vulnerable personality."

Dr. Marmor also indicated that the "early rich hopes of the psychoanalytic revolution have not been fulfilled. . . . Its results have been relatively disappointing."

Dedicated psychoanalysts have attempted to modify Freud's classical approach by "increasing flexibility, modifying the frequency of visits, allowing patients to sit up during therapy, interviewing significant others, controlling transference regression, modifying noxious environmental factors where possible, and functioning as participant observers." It seems that the more psychoanalysis changed, the more it resembled Adolf Meyer's psychobiology.

All these changes in psychoanalytic technique were necessary and helpful. But is the final result of these modifications still Freud's "psychoanalysis"? Freud would have differed. He was cognizant of the analyst "who attempted to emphasize some single one of the findings or views of psychoanalysis at the expense of all the rest." Of one such modifier (Jung) Freud wrote, "He has changed the hilt, and inserted a new blade into it, and because the same trademark is engraved on it, we are required to regard the instrument as the former one" (1).

Dr. Marmor's paper is a scientific and humanistic tour de force. He is to be congratulated for presenting his clinical astuteness and holistic philosophy in the best possible format.

The Voting Mental Patient

SIR: In light of the upcoming national elections, I thought it appropriate to consider the voting status of psychiatric patients. How many of the psychiatric patients who are hospitalized exercise their voting rights? How many patients have the right to vote taken away from them by legal means (commitment or otherwise)? Do states differ in dealing with aspects of the voting processes of patients? As elections approach, how many hospital directors provide literature from various political parties on the candidates or arrange for transportation to and from registration and the polls?

If the 1960s were the decade of voluntary admissions and back to the community movement, the 1980s should be the decade of civil liberation and the voting mental patient. All patients should be given the opportunity and encouragement to exercise their rights. Perhaps legislators would not be so slow to appropriate funds for hospitals and mental services if we made them aware that hospitalized patients are an active part of their constituencies. Political rallies at hospitals could have tremendous therapeutic effects, bringing mental patients back into the mainstream of American life. In certain local situations with close results at the polls, the patients of the mental hospitals, viewed as a deciding force, could become the targets of vigorous campaigning, forcing candidates into promises of action on their behalf.

VICTOR BERNAL Y DEL RIO, M.D.
San Juan, Puerto Rico

Identifying Pseudoseizures with Anhydrous Ammonia

SIR: Anhydrous ammonia has long been used in general medicine as a respiratory stimulant. Three recent cases suggested to us that it may have a value in psychiatry as well. However, we were unable to find any reports in the literature of its use. We request the assistance of *Journal* readers in locating references for the use of ammonia.

Case 1. Ms. A, a 26-year-old woman, was hospitalized for treatment of marital problems and secondary depression. After a stressful therapy session she fell in the hall. She exhibited jerking movements of the extremities, not typical of clonic movements. Her eyelids fluttered. She would not respond to verbal or painful stimuli. Her pulse and blood pressure were normal. One ampoule of anhydrous ammonia was administered. After one breath Ms. A opened her eyes and began talking. She complained of lightheadedness but remained alert thereafter.

Case 2. Ms. B, a 17-year-old woman who met *DSM-III* criteria for paranoid schizophrenia, had been taking haloperidol and benztropine mesylate intermittently. She was brought to the emergency room where she was found to have decreased spontaneous movements, cogwheel rigidity, and conjugate deviation of her eyes to the left. The most likely diagnosis seemed to be acute dystonia due to phenothiazines. However, Ms. B's medical history was vague enough to suggest a functional symptom, so one ampoule of ammonia was tried. After one breath she immediately turned her head and gazed at the physician. After a second breath Ms. B stood up and said she felt fine. She exhibited no signs of dystonic posturing during a 40-minute period of observation. Neurological reexamination revealed no abnormalities, and cogwheel rigidity had completely disappeared. Ms. B's deep tendon reflexes were brisk but symmetrical (3−). During another 40-minute period of observation no dystonic posturing recurred.

Case 3. Alfie, an 11-year-old boy, was admitted to a pediatric neurology service for evaluation of "spells" consisting of sudden onset of shaking, gasping, and crawling on the floor with eyes closed. He would not respond to verbal or painful stimuli during the spells, which usually began during tantrums. When a thorough workup, including EEG, CT scan, SMA-20, IVP, GTT, and 24-hour Holter EEG, yielded normal results, the neurologist believed his initial impression of pseudoseizures was confirmed. Treatment with saline injections had no effect on Alfie. During one spell an ampoule of anhydrous ammonia was administered. Alfie took one breath and his spell was immediately aborted. About 12 hours later another spell occurred and a second ampoule of ammonia was administered. After one breath Alfie stood up and said, "I don't need that; just give me the shot." No further spells occurred during the next 48 hours.

Under usual circumstances the patients we described would have received intramuscular injections for their symptoms. In cases such as these anhydrous ammonia may aid in the identification of pseudoseizures and other functional symptoms and render intramuscular treatments unnecessary. We would be particularly interested to hear from readers who have had experience with this management technique or who may know of relevant publications.

Corrections

On page 641 of the book reviews section in the May 1980 issue the title of the book by Henry Kellerman, Ph.D., was listed incorrectly. The correct title is *Group Psychotherapy and Personality: Intersecting Structures*.

On page 651 of the May 1980 issue, in the list of those who successfully completed the examination of the American Board of Psychiatry and Neurology, the name Jong Jin, Marvin Young should have been listed as Jin, Marvin Young Jong.

The staff regrets these errors.

BOOK REVIEWS

Crisis Admission Units and Emergency Psychiatric Services. Public Health in Europe 11, *by J.E. Cooper. Copenhagen, Denmark, World Health Organization (Albany, N.Y., WHO Publications Centre USA, distributor), 1979, 118 pp., $6.60 plus $1.25 for postage and handling (paper).*

This book contains a comprehensive description of 15 emergency and crisis services in 8 European countries. These services range from psychiatric facilities without a distinct or separate emergency ward to sophisticated crisis units with overnight beds. When applicable, the author also describes the service delivery area, the physical arrangements and organization of the facility, the aim of the unit, the personnel, the patients, the record-keeping system, and related research and training. Emphasis in the discussion is on staffing models and issues. The author describes the organization of these units along a continuum from "the conventional medical," which maintains a vertical hierarchy, to the "unconventional social," which is based on a horizontal structure and involves teaming and sharing of clinical responsibility. Particularly informative are the sections on staff satisfaction, which discuss many of the issues involved in interdisciplinary teaming such as the blurring of professional roles.

Although the volume begins with a somewhat sketchy summary of crisis theory and practice, the focus in the book is on an organizational description of services and staffing rather than a discussion of various crisis intervention psychotherapy approaches. This manual fills a gap in the literature on emergency service delivery by pulling together materials that are usually widely scattered or generally unavailable. The format of the book makes the information easily retrievable. The appendixes, which contain a bibliography describing emergency service delivery and a comprehensive directory of the names and addresses of the directors of the European programs, provide additional useful information.

I highly recommend this manual as an excellent resource for anyone currently involved with organizational issues in an emergency setting and for those thinking of developing a crisis service.

ELLEN L. BASSUK, M.D.
Boston, Mass.

Parents and Children in Autism, *by Marian K. DeMyer. Washington, D.C., V.H. Winston & Sons (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1979, 262 pp., $17.95.*

Dr. DeMyer is a well-known and respected authority in infantile autism. This volume is the product of her many years as Director of the Clinical Research Center for Early Childhood Schizophrenia, Indiana University School of Medicine. Data are presented on long-term studies of 155 families with autistic children; they are compared with matched families with normal children and matched families with nonautistic retarded children.

The book is not primarily a research report, although the author is familiar with the major research trends in the field and presents brief summaries of her own studies. Rather, as she puts it,

> This book traces the clinical course of autism from birth to adulthood and parental reactions and behavior from the mother's pregnancy through life with an "adult child." Empirical data are supplemented by case histories to illustrate some of the most typical features of the disorder. I have tried to show the many facets of normal and autistic development by using the eyes and the words of parents whose observations are too often underemphasized in psychiatric writings.

Dr. DeMyer succeeds admirably in her purposes. Her style is informal, even conversational, and refreshingly free of professional jargon. Her clinical expertise and sensitivity to her child patients and their parents are evident throughout. The individual chapters take up the problems and symptoms at successive age periods and in specific areas, such as speech and communication, feeding and eating, elimination and toilet training, sleeping, social behavior, emotional expression, discipline, and intelligence. There are careful tabulations of the incidence of these problems, the nature and intensity of parental concerns, and the approaches used by parents in handling the child's symptoms and difficulties. Wise, empirical advice is offered throughout. Many brief and pertinent clinical vignettes illustrate the issues discussed.

Although the author tries to maintain an optimistic approach, she does not hide the reality of the bleak prognosis for most cases of autism and the extraordinary stresses imposed on parents and siblings who live with and care for an autistic child. In line with other recent research findings, Dr. DeMyer's reports of her own comparisons of the personality characteristics of autistic and control parents show no significant differences between the two groups. However, she emphasizes that the parents of autistic children face enormous difficulties and pressures in rearing these children and that "such multiple stresses, continuing over months or years, had effects on the parents as individuals and marriage partners and eventually on the other children in the family" (p. 150). Of special interest are the chapters detailing the new problems and stresses the autistic child faces as he or she goes through adolescence and enters adulthood. In some cases, however (a small minority), there is significant and even dramatic improvement during these older age periods.

This volume can be highly useful to all professionals re-

sponsible for the care and treatment of autistic children. It can also be recommended to sophisticated parents of such children.

ALEXANDER THOMAS, M.D.
New York, N.Y.

Nim, *by Herbert S. Terrace. New York, N.Y., Alfred A. Knopf, 1979, 291 pp., $15.00.*

For the person who is unfamiliar with the problems involved, the hours spent, and the endless devotion necessary to try to teach a chimpanzee to communicate, this is an excellent book. The author and his colleagues spent more than four years in the task and another year analyzing their findings. Theirs was a thorough and courageous effort that only an informal account can capture.

The aim of the author's project was to demonstrate that a chimpanzee can create a sentence by communicating in sign language. Such aims carry their own set of methodological and conceptual burdens, and the author is well aware of them. For example, is the concept of "sentence" well enough defined to establish criteria for judging a chimpanzee's signs? Is it appropriate to compare chimpanzee signing to human utterances or does one have a choice? If one is using human teachers to teach sign language can he ever be certain that subtle communications are not predetermining a chimpanzee's signing sequences that others are taking as indications of sentence formations? A variety of attempts have been made to confront and, at times, avoid these problems through such means as token and computer communication, but in the attempt described in *Nim*, as in all previous attempts to determine if chimpanzees can create sentences, the findings remain ambiguous.

That the author was never fully satisfied that he achieved his aim makes the book no less interesting. His accounts of his frustrations, joys, and sorrows make *Nim* worthwhile reading.

MICHAEL T. MCGUIRE, M.D.
Los Angeles, Calif.

Women: Psychology's Puzzle, *by Joanna Bunker Rohrbaugh. New York, N.Y., Basic Books, 1979, 491 pp., $15.00.*

The author of this book is a feminist and a careful and thorough scholar. This lengthy, closely printed text contains quotations from approximately 50 sources ranging from articles published in *Ms.* magazine to Freud's original papers, as well as many footnotes. The 22-page bibliography should, itself, be of great value to anyone who undertakes teaching "women's" studies as well as to the much larger group who speak on subjects of interest to women.

This generally excellent but pedantically written book covers all of the usual material in considerable depth. Psychiatrists will find the section on theories of female personality of particular interest. Dr. Rohrbaugh discusses women in psychoanalytic theory. She reviews cognitive-developmental and social learning theory in general and as they relate to women in our society. In "Woman's Place in Society" Dr. Rohrbaugh goes beyond the usual presentations regarding the dilemma of women, marriage, motherhood, and the single state (including lesbianism) to include working women and minorities.

In her chapter on "Third World Women" Dr. Rohrbaugh empathetically discusses the situation of black women in the United States and the concepts of black matriarchy and black macho. She concludes this chapter with a strong opinion:

> It is time for social scientists to examine the black experience from the viewpoint of blacks, themselves. It is time to stop imposing white, middle-class values on millions of Americans who do not necessarily share them. And, it is time, some would add, for black women to act on their own behalf. (p. 264)

This emphasis on the need for social scientists, physicians, and mental health workers, especially researchers in all of these fields, to consider "women's own opinions and experiences" is evident throughout the book. Sexuality, birth control, pregnancy, rape, the battered woman, and women's activities in sports are all carefully covered with a strong feminist focus.

The psychiatrist, especially the psychiatrist in private practice, will find Dr. Rohrbaugh's section on women and mental health of great interest. She discusses hysteria as superfemininity and poses questions as to why men with social charm, the ability to manipulate other people, and a lack of guilt for their actions are considered psychopaths instead of hysterics. She also writes about several other "female" mental illnesses, including depression, anorexia nervosa, and phobias.

Most interesting is Dr. Rohrbaugh's presentation of feminist therapy—both individual therapy and consciousness-raising groups. To quote her: "One of the central tenets of feminist therapy is that the therapeutic relationship should not involve power. A therapist should neither be a patriarch nor dominate or intimidate a client" (p. 445). Of consciousness-raising groups, in particular, Dr. Rohrbaugh states, "I would say that CR is not group therapy, nor is it appropriate for everyone, but it is a positive alternative to traditional psychotherapy for the millions of women who are seeking personal growth" (p. 461).

Dr. Rohrbaugh, a well-trained psychologist who is currently in private practice in Boston, teaches courses on the psychology of women and women and mental health at Harvard. She has produced a scholarly and thoughtful book that cogently presents current feminist views. The book represents a sound reference for psychiatrists who seek to understand feminist thinking.

Plainfield, N.J.

Becoming Female: Perspectives on Development, *edited by Claire B. Kopp with Martha Kirkpatrick. New York, N.Y., Plenum Press, 1979, 461 pp., $25.00.*

If the research data reported in this book about becoming female and becoming male were tabulated, it seems to me that one would find an equal amount of information about the development of women and men. Thus the subtitle, *Perspectives on Development*, with the additional words female and male, aptly summarizes its contents. One of the greatest

strengths of the book is its fine review of some areas of research literature, particularly of the past 10 years, on issues of importance in male and female development.

The book is divided into four sections: Identity and the Immediate Environment, Characteristics, The Larger Environment, and Biological Considerations. There are 24 contributors representing 10 professional disciplines. There are 8 psychologists, 2 or 3 educators, sociologists, pediatricians, experts in women's studies, historians, and 1 expert each in public health, child psychiatry, anthropology, and genetics. The uniqueness in perspective of experts from such widely differing disciplines is reflected in each person's scholarly approach to the topics. In some instances, these differences in scientific methodology may pose problems for the reader, who must change to a different cognitive orientation for each author. On the other hand, the reader might find that these variations lend richness to the book.

An intriguing aspect of the book is the blend between some authors' professional expertise and their personal identification with the topic. This blend shapes the presentation. One example is the chapter "Growing Up with a Physical Handicap," which is a highly personal autobiography by Shirley Sargent, a historian, who developed the physically and psychologically painful dystonia musculorum deformans during childhood. Another example is Gloria Powell's chapter "Growing Up Black and Female," which crosses the border back and forth between a sociological, historical approach to the Afro-American woman as black nanny, black mammy, beast of burden, prostitute, and the wicked witch and a personal commentary about the intimate meaning of being black for the author. Dr. Powell demonstrates that the interaction between men and women can have a mutually destructive effect.

The book opens with a remarkably clear articulation of the development of identity by Phyllis Katz. She describes the varying psychological theories of sex role acquisition, including the effects of direct reinforcement, modeling processes, identification (anaclitic and defensive), and, finally, the cognitive developmental view in which the child recognizes himself or herself as girl or boy. Dr. Katz then analyzes the problems inherent in these theoretical constructs and offers an alternative theoretical model of three levels of sex roles. Such an analytic approach to a topic with a comprehensive review of the research literature is most evident in the articles by the psychologists.

I thought the chapter titled "Sex-Related Differences in Spacial Ability: A Developmental Psychological View" by Lauren Harris an exceptionally fine presentation about verbal-linguistic ability as well as visual-spacial ability. Dr. Harris examined these topics from viewpoints ranging from those in the social experiential literature to those in the biochemical genetic literature. The thoroughness with which he reviews the literature is indicated by the length of the chapter (48 pages) and the extensive bibliography.

The chapter "Effects of Observed Violence on Females: A Critical Review" is similar in its level of analysis of the problem, lengthy bibliography, and the fact that it poses questions rather than answers. Susan Franzblau points out that although the television female symbolizes altruism, she also signifies passivity and, often, victimization. Although the television male plays the violent perpetrator and plays him successfully, he also represents competence and power. In the real world, the primary victims of males are males, not females. The TV portrayal of female victimization is a distortion of the real world, adding even more confusion and ambivalence to the already murky picture that females have of their role responsibilities. The author concludes with a theory that the effect of television on females may be to activate pro-social responses that increase with age.

In addition to the aforementioned authors, an attitudinal approach that stresses the continuing need for the development of hypotheses and carefully designed research is demonstrated in the presentation of some individual authors' research projects. Examples include "The Role Music Plays in Adolescent Development" and "The Role of Laughter and Humor in Growing Up Female." The other articles serve an overview function and include the following topics: father-daughter and mother-daughter relationships, female delinquency, play of girls (and boys), women geniuses, cross-cultural perspectives, genetics, clothing, physical growth in adolescence, and nutrition.

A poignant, thought-provoking commentary about these current perspectives on human development are the brief excerpts, mainly by writers from the latter half of the nineteenth century, that are given at the beginning of each chapter. These Victorian quotations reminded me of probably the most famous Victorian story of all, about a girl named Alice who learns about a new world through following a male rabbit. Alice tries constantly to control her growth and the impact of her behavior on others. In her answer to the blue caterpillar's question, "Who are you?" Alice comments that she knew who she was when she got up in the morning but she can no longer understand herself since she is constantly changing. She pointedly remarks that the caterpillar will understand her once he has also had to undergo a metamorphosis. Finally, she questions whether he, even now, knows who he is. The continued popularity of *Alice in Wonderland* reflects the fact that each of us becomes puzzled and confused at varying times in our lives with the problems of controlling growth and development, our social interactions, and differentiating the real from the imaginary. This book offers a series of readings placing these problems of women and men in contemporary social context.

Indianapolis, Ind.

Working with Dreams, *by Montague Ullman, M.D., and Nan Zimmerman. New York, N.Y., Delacorte Press/Eleanor Friede, 1979, 323 pp., $10.00.*

Working with Dreams is written for the lay reader who is interested in the interpretation of dreams and the use of dreams in daily life.

The book is essentially divided into two sections. The first is a remarkably clear, concise, and easily understood exposition of contemporary theories of the phenomenon of dreaming, its physiological correlates, and methods of interpretation.

In the first section Dr. Ullman presents a lucid and detailed comparison of the differing perspectives of Freud, of Jung, and of himself. He compares and contrasts these views in relationship to the theoretical aspects of dreaming and the clinical interpretation of dreams. Although he emphasizes his differences with Freud and his greater sympathy with Jung, an examination of the differences seems to reveal a continuing allegiance to Freud.

The second half of the book, aside from a chapter on precognitive and telepathic dreaming, is largely a description of the way Ullman and his coauthor, Nan Zimmerman, have organized dream study groups in which members present their dreams for "group analysis."

This method is indeed useful, as I know from my experience with the use of actual dreams of the patients of candidates in a psychoanalytic seminar. The clinician who offers a dream from a patient is often rewarded by a wealth of relevant associative material from his or her colleagues. Nevertheless, I have serious reservations about the function of the dream study groups that the authors describe. First of all I am not convinced that expertise is as unessential to useful dream understanding as they seem to suggest. The use of dreams in such groups as the "dream people" of Malaya described by Noone and Holman (1) is entirely different: ritual formulas are used in the interpretation of the dream, adding a measure of safety that Ullman's groups, with their more personal and more idiosyncratic interpretations, do not provide. Furthermore, there seems to be a degree of distress initiated in some individuals in Ullman and Zimmerman's groups, which, although passed over rather lightly, I found of concern. Finally, it is not at all clear, as the authors themselves suggest, whether it is the beneficial results of the communal dream analysis or of the more traditional group process that holds the group together. I feel too little attention is paid to the latter element, and I believe this in itself constitutes a danger.

I suppose that my basic concern with the book's second section centers about what Ullman and Zimmerman enthusiastically espouse, namely, a lay approach to the use of dreams to illuminate and guide our daily lives. I, too, believe all people should pay attention to their dreams as a wonderful and creative aspect of their experience. This, however, is different from a formal study group in which even the expert, which Dr. Ullman certainly is, insists on denying his experience and expertise and refuses a role as leader. The object of this work is said to be non-"clinical"; yet the process itself, as with so many other projects in which so-called "elitism" or "professionalism" is decried, exists in a borderland fraught with risk.

Boston, Mass.

The Broken Connection, *by Robert Jay Lifton. New York, N.Y., Simon and Schuster, 1979, 466 pp., $15.95.*

Continuing in Freud's tradition of trying to explicate clinical data, Robert Lifton, eminent psychiatrist and author, essays a new psychology based on mankind's symbolizing of the life cycle. In so doing he hopes to obtain a new paradigm. Lifton seeks "general principles concerning death imagery and struggles for continuity." The book is divided into prologue, parts one, two, and three, epilogue, and appendix. It is heavily annotated and tightly written.

In the eight chapters of part one Lifton compares various concepts of death and immortality. He concludes that it would be better to speak of a "sense of continuity" than a "sense of immortality." He wishes to trade the concept of "instincts" for what he calls "the inchoate image." This latter term he defines as "man's innate plan as a cultural animal." Such a change would replace the concept of "castration anxiety" with a more inclusive term, "death anxiety." Death images begin at birth and continue to be experienced throughout the life cycle. Images of death equivalents include such things as images of separation, disintegration, and stasis. Each of these images of death has an equivalent counterpart associated with vitality. Thus connection is associated with separation, integrity with disintegration, and movement with stasis. Lifton ably reviews the traditional psychosexual stages of development and reinterprets the developmental tasks and experiences in terms of his new paradigm. With an Eriksonian flair, he continues this into adolescence and adulthood. His chapter on "Culture and Connection" is particularly lyrical. He expresses here his belief that death equivalents and life parameters have a biological origin in the inchoate imagery but are embedded in cultural symbolization. He demonstrates this by describing funerary customs among the traditional and more modern Japanese and compares these with modern American customs. Buddhist tradition is compared with the Judeo-Christian.

In the 10 chapters of part two of the book, Lifton applies his outlined system to concepts of fundamental emotions. He also extends this to the neuroses, schizophrenia, and the phenomenon of suicide. This was the most interesting part of the book to me, and I think it will be to any practicing psychotherapist. Chapter 11, titled "Guilt," is a masterpiece. Lifton observes,

> The pragmatic-secular-optimistic constellation characteristic of much of American life makes the experience of guilt virtually a sin. And this in turn contributes to the susceptibility of young Americans to movements demanding that they wallow in guilt. In any case, guilt has acquired a not entirely undeserved bad name.

Lifton compares the guilt of two survivors of extreme situations, a Viet Nam veteran who had been at My Lai but who did not fire his gun and a "zealot saint" of Hiroshima. Lifton is at his finest in reevaluating some of the classical Freudian cases, redefining schizophrenia, and reexamining the Buffalo Creek disaster and the Hiroshima atomic bombing. His own work with survivors of these latter two horrors permits him to speak with great authority. There are many useful data on survivor trauma for the practicing therapist. One chapter is devoted to Yukio Mishima, a serious contender for the Nobel Prize in literature who dramatically committed seppuku in 1975. Lifton uses him as a case history to illustrate his thesis. The attempt is convincing.

In the 5 chapters of part three Lifton examines "broader historical phenomena around the theme of death and continuity." He points out our sense of awareness that we have weaponry which could totally wipe out mankind and postulates a "psychic numbing." It is as if all people were beginning to act like victims. He makes a strong case by reviewing the impact of the continual threat of death on traditional historical victims. This worldwide psychic numbing has resulted in the "ultimate contemporary deformation—a condition we may call nuclearism." Modern man attempts to deal with his death anxiety regarding nuclear weapons by seeing salva-

tion as well as ultimate destruction in nuclear weapons. Ultimate salvation includes such things as the uses of nuclear power to solve the energy crisis and hopes for nuclear technology that will revolutionize modern medicine.

A four-part appendix concludes the book. Appendix B, "Death Imagery and Psychosomatic and Character Disorder," is of further interest to the clinician. Lifton extensively quotes a 1963 article by Elliot Luby, who sees Lifton's work as "very compatible with our paradigm." Appendix C, which includes historical notes on schizophrenia and death, is also thought-provoking.

This is a brilliantly written work of scholarship. Despite its being well written, I found the book difficult to read (death anxiety?). About halfway through the book I noticed that the color of its cover, by accident or by design, reminded me of the vestments and artifacts traditionally used in the requiem mass in the Roman Catholic Church.

In summary, *The Broken Connection* is a seminal work that will probably be referred to for some years to come. Whether or not it will establish a new paradigm will depend, I think, on Lifton's further working his thesis. I highly recommend the book.

PHILIP E. VEENHUIS, M.D.
Wauwatosa, Wis.

Annual Progress in Child Psychiatry and Child Development 1979, *edited by Stella Chess, M.D., and Alexander Thomas, M.D. New York, N.Y., Brunner/Mazel, 1979, 690 pp., $20.00.*

This is the eleventh year of the *Annual Progress in Child Psychiatry and Child Development*. It continues the labor of love undertaken by its editors over a decade ago with their devotion to children and their recruitment of others to their cause. Each volume has changed as the emphasis of the professional's interest in children has shifted from year to year. The editors have made a significant contribution during these years by permitting their selection of articles to reflect the changing interest of professionals as well as attempting to identify significant contributions to the ever-expanding scientific literature about children. Thus an examination of the current volume not only exposes the reader to a collection of 37 articles in 11 major areas but also serves as a signpost of where we are now, where the field seems to be going, and where some of the inadequacies are in our overall efforts to address ourselves to the problems of children.

The areas of interest include infancy studies, developmental issues, language cognition, temperament studies, family studies, the hyperactive child, mental retardation, clinical issues, delivery of services, and adolescence. There is a heavy investment in the presentation of developmental issues, reflecting our growing preoccupation with the nature of the child and the need for reexamination of concepts in the light of the inadequacies of our efforts to identify childhood disorders. The content of other articles appears to be related to the intensified interest in early childhood development by professionals from the disciplines of psychology and education. The transition in content of past and present volumes appears to be determined as much by this newly developing unity among professional disciplines as by shifting interests. A reading of the current volume compared with some of the earlier ones shows this change extending to language use as well as techniques of research.

A number of the articles warrant special mention, but by so doing I do not wish to take away from the general level of excellence among the others. The best of the articles appear to be those clearly identified as reviews of a particular subject. Important issues are raised and historical presentations of the subject are developed so that the reader can use this volume as an effective instrument for reference or review of such subjects as neonatal assessment procedures, concepts of human development, nonverbal communication, hyperactivity, childhood depression, anorexia nervosa (the bibliography is excellent), day care, and adolescent theory.

With the limitations of a book made up of the writings of many different authors with different styles, points of reference, and philosophies, the 1979 volume of *Annual Progress in Child Psychiatry and Child Development* is a contribution to all of us interested in children.

SOL NICHTERN, M.D.
New York, N.Y.

Theoretical Criminology, by George B. Vold, 2nd ed., *prepared by Thomas J. Bernard. New York, N.Y., Oxford University Press, 1979, 422 pp., $14.95.*

Preoccupation with the cause of crime has been the bête noir of sociologists, psychiatrists, physiologists, and penologists as well as judges, legislators, and the concerned citizen. The tremendous amount of thinking and writing on this intriguing subject for almost three centuries has not yet yielded a satisfactory, unitary theory; therefore, treatment of criminals has been equally unsatisfactory. Professor Vold, whose work has been posthumously updated and edited by sociologist Thomas Bernard and aided by additions necessitated by new researches since the original book was published in 1958, surveyed the chaotic scene objectively and deftly.

Professor Vold, who died in 1967, was held in high esteem by sociologists and criminologists. He summarized the unwieldy mass of information and theory on crime causation with simplicity and honesty, placing psychological, biological, and social theories in perspective. His book is a pleasure to read; its treatment of that cumbersome, complex group of behaviors, united only in being nominated by law as "crime," is a model of clarity. Vold offers no dogma, no final solutions, no priorities, only a measured exposition of theories that never seem to cover all facts surrounding man's perpetual wrongdoing.

The early chapters outline the various schools. The classical school (Beccaria), which advocated "equal punishment" for "equal crime," was based on the theory that a criminal could make a rational choice of conduct. The anthropological school (Lombroso, Goring, Hooton) held structural differences (dysplasias) responsible for crime. The psychological school believed that mental deficiency was basic for crime. The psychiatric theory held that personality distortions and "psychopathy" underlay criminal action. The more recent psychoanalytic, dynamic interpretation of crime by many authors postulated an "acting-out" of neurotic character distortions. In general, Vold held that biologic-psychologic explanations have limited usefulness.

The author examines the economic theories of crime cau-

sation, e.g., "poverty causes crime" and the more recent ecological theories positing that "invading and retreating cultures," clashing in a spreading city generate conflict that eventuates in crime, especially among young people. The work of the Chicago school of sociologists is accented; this school held that conditions of life in a city with changing ecology form criminal patterns. Following this, the author discusses the anomie tradition of Durkheim and Merton, who held that a breakdown in regulation allows and even encourages members of the society to achieve their goals outside the law, as in embezzlement, fraud, and cheating on one's income tax, the so-called white-collar crimes.

The discussion then moves to criminal action as "learned behavior" (Lindesmith, Sutherland), according to which the accent is on community influence rather than individual deviance or abnormality of personality. Learning by association, i.e., Sutherland's differential association theory, was, according to Vold, "an exciting episode in criminological thinking," which has yielded during the recent past to the interactionist (Mead) and group conflict (Vold) theories of crime. The former holds that what social situations mean to the individual is vital in explaining his or her behavior, and the latter insists that there is a "shifting . . . equilibrium of opposing group interests in society" and that these "endless interactions of moves and counter-moves" become the essential element that gives rise to crime. The law-abiding group, through the legal process, forms the law and defines crime, while other subgroups conflict with the majority position to attain their own satisfactions.

The group conflict hypothesis was Vold's own development—"normal antagonisms and conflicts of human groups"—represented in the struggle for political power and concretized in cultural institutions such as the law. However, the author makes it clear that the group conflict theory holds chiefly where criminal acts "flow from the collision of . . . in-groups" and out-groups. In other words, "The enactment and enforcement of laws . . . [is] the result of the conflict and compromise process as each group struggles to enhance its own position." A contemporary development of the conflict theory entails a discussion of Marxist philosophy of political organization, whether laws are formed to protect a privileged class ("criminal law is the tool of the politically dominant") or a consensus of an enlightened electorate, as the classical school insisted.

The essential problem that Vold and his editor faced in this work is whether a criminological theory can be evolved on the basis of social and/or cultural research, which tends to be "divided between meaningless specifics . . . and broad generalizations." In his summary Vold concludes that no one theory explains the wide diversity of misbehavior that is called crime until more exact definitions and measurements of social pressures on individuals can be devised.

For the psychiatrist who has struggled, as I have, with criminal action as psychologically determined, it is arresting and stimulating to consider the broader canvas of social theories of crime. The book is devoted to theory, whose importance is its foundation for treatment, which we must admit has been anything but successful over the decades. Professor Vold's book, with the additions by his followers, is a necessary tranquilizer for the forensic psychiatrist who is afloat in the squally sea of criminality.

WALTER BROMBERG, M.D.
Sacramento, Calif.

New Developments in the Use of the MMPI, *edited by James N. Butcher. Minneapolis, Minn., University of Minnesota Press, 1979, 390 pp., $27.50.*

This volume is a collection of papers by authors with special expertise in the use of the MMPI in the various areas discussed. Many of these papers were presented at a 1979 symposium on recent developments in the use of the MMPI in St. Petersburg, Fla. The 10 chapters cover a wide range of issues, starting with a very technical chapter by Mary Koss, who discusses MMPI item content, issues, and problems. This is followed by chapters on the clinical use of the MMPI, including one on the evaluation of personality changes with the aging process by Gynther, "Ethnicity and Personality," also by Gynther, "Use of the MMPI with Medical Patients" by David Osborne, "Use of the MMPI in Personnel Selection" by James Butcher, and "MMPI in the Evaluation of Treatment Effects" by Steven Hollon and Monica Mandell. There are two chapters on the use of the MMPI in the classification of criminal offenders, one by Edwin Megargee and one by Raymond Fowler. These discuss the use of a computerized interpretation of the MMPI in correctional decisions.

The last few chapters are primarily research oriented, one by James Butcher and Lee Anna Clark on recent trends in cross-cultural MMPI research, and a very interesting chapter by David Lachar and James Sharp on the "Use of Parents' MMPIs in the Research and Evaluation of Children." Finally, there is an excellent bibliography of MMPI research organized by such topics as affective disorders and related studies, organicity and intellectual functioning, and treatment outcome.

The generally high level of the material presented in this volume is, I believe, a tribute to Dr. Butcher's careful editing and his encyclopedic knowledge of the field. Although much of the material contained in the volume would be of interest primarily to individuals using the MMPI in research activities, there is important, clinically useful information in several of the chapters that will be valuable for clinicians working in the areas of corrections, in general medical settings where assessment of the personality problems of patients may be of importance, and for clinicians using psychotropic medications in treatment and in clinical trials.

Although this volume would not be recommended for inclusion in every psychiatrist's library, it certainly should be available for reference in mental health centers, in psychiatric hospitals, and in general hospitals with psychiatric units and active psychiatric-liaison services.

BERNARD C. GLUECK, M.D.
Hartford Conn.

Existential Foundations of Medicine and Psychology, *by Medard Boss; translated from the German by Stephen Conway and Anne Cleaves. New York, N.Y., Jason Aronson, 1979, 297 pp., $20.00.*

This is a difficult book to comprehend, in part because of the unfamiliarity of most American readers with existential philosophy and psychiatry. The paragraphs that follow are intended to present some of its principal contentions and to put them into the perspectives of more familiar schools.

A useful starting point is the existential description of pa-

thology. Every disorder, from a broken leg to schizophrenia, is described from the existential viewpoint in its impact on human freedom, by which is meant one's ability to relate fully to the world or, in Boss's language, to have access to the modes of being in the world. These modes or basic human characteristics include the ability to move through space and time (and not only measurable space and time, but the ability to imagine absent spaces and times), accept uncertainty and mortality, coexist in a shared world, and reach an affective attunement. Descriptions of pathology are descriptions of impingements on these modes, and the therapist's responsibility, whether as surgeon or psychiatrist, is to place himself or herself with the patient in the task of restoring human freedom. In other words, pathology is here described in terms of the *highest* human functions rather than the lowest. It is not that the "lowest" (for example, a metabolic defect) are not important; many, of course, are fatal. The point is that they cannot describe what is human.

The advantages, Boss argues, of retaining human reference points for descriptions of pathology are several. Human reference points direct attention to large-scale impingements on freedom that make reductionistic lesions secondary or symptomatic and their corrective measures ineffective in the life of the patient as a whole. Boss is not against setting fractured legs. What he means is that many fractured legs are symptoms of accidents, which in turn are cries for help of beleaguered individuals. The surgeon must place himself or herself with the patient in the world unless he or she is to be a mere technician who will all the more readily, Boss fears, become an agent of state medicine and lose the great role of healer.

Human reference points make possible a real locating of the patient and therefore of joining him or her in the task of liberation. Every reductionist view, whether the reduction to chemical events or psychic complexes, threatens not only our grasp of the patient's whole situation but also our ability to get with him in its correction. Here the classic illustration is the patient hurried through and out of the university clinic; a rare defect is discovered, but the patient never has the opportunity to voice his chief complaint. The first goal of the existential healer is to see the world from the patient's point of view. This may mean concentration on the broken leg (to which the painful member had reduced the patient's world), but attention cannot as a rule remain there long. Once the acute phase of the illness is over, the healer seeks to share the patient's now enlarged world. It may be there *is* no enlarged world; the concentration on the leg continues, as in some hypochondriases. Or the patient's world may open up to full human freedom and the healer is dismissed, but there may be specific impingements that need attention.

Boss's accounts of phobias are illustrative. Emphasis does not fall on intrapsychic conflicts or environmental conditioning (much as these may shape the choice of the specific phobia) but on the underlying attitudes, for example, narcissistic expectations that make any interruption, breakdown, or intrusion a feared attack on the patient's entitlement always to expect changelessness, safety, even immortality. This is not Boss's language. He writes of the agoraphobic person's inability to tolerate large open spaces because in fact it is from these that "unfamiliar and uncertain things" may enter. The point is the same: the agoraphobic person is accused of having a brittle character or world outlook. Psychoanalytic and behaviorist treatments may be effective, but Boss implies this is because both provide the brittle patient with an ally against uncertainty. The existential claim, which I have seen sustained enough not to dismiss it, is that the same result can be achieved more fully and directly by allying with the patient in his world view and then helping him gradually to modify it.

The existential view is curiously like the medical view. Both see the patient as impinged upon: in the medical view, by bacteria, viruses, cancers; in the existential view, by these and, as well, other people, social systems, etc.

The human reference indicates not only the substrate of disease and the possibility of being with the patient in his situation, it also provides goals of therapeutic work: the definition of full human freedom. The detail in which existentialists do this should be of special interest to psychiatrists who have had to construct treatment goals from disease concepts or the broad strokes of Freud's love and work.

In different words, the book claims there is an existential and not an exclusively physical science foundation to medicine and psychology. An exclusively physical science foundation, Boss argues, leaves us capable of seeing "only causal relationships among isolated objects." An existential foundation recognizes what Boss believes is the reality of the human state: that its occupants are not isolated objects, their relationships can never be fully quantified or causally connected, and that the goal of their being is a "non-objectifiable openness." At this point existential psychiatry, like all the schools, begins to move within the circle of its own words. Let me attempt a translation. In the human sense, I may be closer to my friend a thousand miles away than I am to the floor I walk on, unless perhaps it is the floor of my home. However, a true measurement or objectification of these psychic distances is probably not possible, although they are often the distances we care most about. My humanness consists not only in my capacity to walk that floor, but also to be close to my friend so far away.

These contentions are challenging and not readily dismissed, but it must be said that Boss seldom makes their acceptance easy. The tone of the book is polemical, at times cranky, and repetitious. Freud's metapsychology is as much an albatross for Boss as it is for many analysts; he cannot leave off picking at it, although the accusations he makes (reductionism, reification, nineteenth-century physicalistic analogies, etc.) are well-known to the literature of all the schools, including psychoanalysis itself. Moreover, Boss's presentation of existential work suffers from the same tone. He does not speak well even of the existentialists. Indeed, he cannot speak of many at all. (The American reader will miss any reference to May, Fromm, Rogers, or Kohut.) Most readers, I suspect, will deplore the "only I know" attitude so epidemic on the present sectarian scene.

I agree with Boss that much theorizing along natural science lines handicaps as much as it equips the practitioner, perhaps especially the psychotherapist. He agrees, too, that the gap between observer and observed favored by some perhaps outdated students of natural science at times provides an obstacle to both understanding and treating. On the other hand, and at other times, the gap between observer and observed is serviceable in that it allows for an objectivity toward the self of great value. Further, I believe it is possible to show that objective and quantitative notions, in other parts of this book disapproved of, are bootlegged in for the purpose of making an often useful way of thinking and working into a general psychology. I believe this last is the abiding sin of all the great schools.

Boss's approach, too, is reductionist in a way he does not appear to notice. The many subtle and useful differentiations of the other schools are reduced to a few general statements that do not allow us to appreciate the intellectual and therapeutic value of the differentiations. (I believe this is especially true of his discussions of transference.) Existential writings often have a flat, broad quality, for all their occasional rising to poetry and philosophy, that does not fit well the uneven terrain of actual clinical work. I write this appreciating that Boss's own clinical work probably does not imitate his conceptualizations. It is very hard to write accurately of clinical work.

Finally, one must acknowledge the many values of the existential viewpoint that this book underlines: existential work, more than any other, appreciates the importance of the *future*; we know, but often refuse to acknowledge, our flimsy structure of *causes* (different causes can produce the same psychopathological picture, and the same cause can produce very different pictures). Further, a heightened understanding of *dreams* springs from seeing them as translations of actual human situations, and the description and understanding of *affects* profits greatly from the phenomenological approach.

If reprinted, the book should be carefully proofread.

Logotherapy in Action, *edited by Joseph B. Fabry, Reuven P. Bulka, and William S. Sahakian. New York, N.Y., Jason Aronson, 1979, 369 pp., $30.00.*

As the title promises, this book is about logotherapy. It is edited and written by followers of Viktor Frankl, who calls himself the "father of logotherapy." Despite the frequent attempts to clarify the nature of logotherapy, there is a peculiar failure to define this special approach to therapy in clinically meaningful terms. Although several contributors attempt to do so, I found myself less than satisfied with their definitions. Logotherapists seem partial to a definition that stresses the term "meaning": "Logotherapy, then, is therapy through meaning (logos)." "Logotherapy is a method to help persons whose life has become empty and meaningless to lead a fuller existence." In addition to defining therapy in these rather restricted terms, logotherapists appear to throw out psychopathology in any usual sense. For them, psychoneurotic or conflict-based illness, psychosis, and all varieties of psychiatrically defined illness are either unimportant or not within the domain of logotherapy. Their preference is to address what they perceive to be an epidemic of meaninglessness that pervades contemporary American culture (apparently more than it does European culture). The task of the logotherapist is to show the client the significant meaning in his or her life no matter how disadvantageous the life situation may be. Furthermore, there appears to be no category of human suffering (as opposed to psychiatric illness) that cannot be addressed through this form of therapy.

It would be easy to dismiss this book were it not for the fact that it is clearly the product of well-intentioned individuals with a variety of backgrounds in counseling psychology training (only Frankl and Gerz have medical training). Although the editors' contention that logotherapy is a widely applied form of psychotherapy is inaccurate with reference to psychiatric outpatient settings, it is undoubtedly being applied by counselors in a number of settings. Unfortunately, no data are provided to allow for a judgment about the extent of its use. From what I could ascertain from the writings of various contributors, it would not surprise me if some individuals with a variety of neurotic disorders were helped by the kind of interventions described in the text. Both of the major technical maneuvers of logotherapy, paradoxical intention and dereflection, are based on the assumption that the will to meaning in life allows individuals to exercise control of their condition by modification of their attitudes, even those toward neurotic symptoms. Gerz used paradoxical intention with a patient incapacitated by the fear of having a heart attack by repeatedly encouraging the patient to make himself have a heart attack. The patient responded by giving up his fear in three sessions. Dereflection was applied in one example to an impotent man who was told that the problem was not serious but he must absolutely restrain himself from intercourse and tell his spouse of the doctor's orders. Released from the demands of sexuality the patient became sexual and potent once again.

These techniques and examples are not totally unfamiliar to clinicians. Psychoanalytically oriented therapists are aware of the occasional need for manipulations, even in analysis. The difference here is that these very short-term interventions are characterized by a lack of attention to the past, the inner emotional life, and, most of all, to the transference. The philosophical core of logotherapy is in fact present in part in psychoanalysis; it is necessary for analysands to accept the fact that the exploration of their symptomatic manifestations, dreams, and affects will add new meaning to their lives. Furthermore, the capacity to tolerate painful affects related to past losses, disappointments, and mistakes is a requirement of a successful treatment.

At this point the similarities cease and logotherapy becomes a form of "wild analysis" in which the transference power of the therapist is used without any apparent awareness by therapist or patient. This schism between logotherapy and clinical psychiatry and psychoanalysis is worrisome to say the least. One can only hope that those individuals with serious emotional distress and needs manage to find their way to therapists whose training permits them to approach their problems in a way that identifies and lessens the influence of pathological trends in the personality.

Finally, it should be noted that the insistence by almost all of the book's contributors that the major "collective neurosis of our time is spiritual" is not nearly as innocent and naïve an assertion as it might appear. This form of externalization has had its appeal to pessimistic social critics, such as Lasch (1), in whose work it reached a peak of expression of the confusion of internal and external problems. Although the insistence that psychiatric problems and suffering result from an attitudinal defect caused by "moral decay" in society may have important repercussions in the hands of a widely read social critic, the effect of such an attitude on a psychotherapist is directly destructive of that therapist's capacity for empathic understanding and for the amelioration of individual suffering through interpretation.

This volume illustrates the unfortunate effect of abandoning the medical model of evaluation and treatment of emotionally based disorders. I consider the counseling psychologists following this system of therapy to be both misled and superficially trained. This new volume will represent a definite disappointment to those who first encountered Frankl in

his moving book *From Death Camp to Existentialism* (2). From that early book it would have been impossible to predict that Frankl and his followers would derive a "supraordinate" theory of therapy that discards an entire corpus of theory and practice in psychoanalysis and psychiatry. That Frankl could find meaning in his experience within the concentration camps was and is moving. Retrospectively, however, his development of logotherapy leads me to wonder whether his assertion that survival was based on finding meaning in experience does not represent an inaccurate, narcissistically based assumption. Perhaps it is chance alone that determines survival in a randomly destructive environment. Psychiatric readers of this book will find little to reflect on that might enhance their clinical effectiveness or stimulate their intellectual processes. Unfortunately, with its few techniques, concepts, and ideas, it might appeal to some individuals whose training is nonmedical as a simplified system of therapy. Patients treated by logotherapy will have received an infusion of a philosophical stance that, while possibly helpful, will deprive them of insight into the nature of their suffering.

Alcohol and Alcoholism, *by the Special Committee of the Royal College of Psychiatrists. New York, N.Y., Free Press (Macmillan Publishing Co.), 1979, 155 pp., $10.95.*

The Special Committee of the Royal College of Psychiatrists is chaired by Dr. Griffith Edwards, who is well known by alcohologists in the United States. The remainder of the committee is composed of distinguished members of the College.

This report was written in response to the awareness of how serious a problem alcoholism is becoming in the United Kingdom. Alcohol consumption per capita rose 87% from 1950 to 1976, and "guilt for offenses of drunkenness" per population doubled. The report is directed to a broad audience, not just a professional audience, and undoubtedly it is hoped that some of those reached will be decision makers in government and health policy councils. Because this is the goal of the report, it is not intended to be a scientific or technical monograph. There are no references to supportive literature, but a bibliography is provided for further reading. Anyone familiar with the field will not find new information. It is not a book on how to do it. However, it is broadly educational for those not so familiar, and that is the purpose of the report. Because it is about the drinking problems of England and Wales, it is an excellent review for anyone interested in cross-cultural studies of alcohol use and misuse.

"Alcoholism," as used in this report, embraces not only the dependence syndrome but also alcohol-induced impairment. I was therefore surprised to learn that there are "only" 300,000 to 500,000 people so inflicted in England and Wales, which have a population one-fourth that of the United States, where we estimate a prevalence of more than 10,000,000 when this more inclusive definition is used.

Although they make passing reference to "Dr. Anstie's limit" (that of a nineteenth-century British physician) of three ounces of whiskey or half a bottle of table wine or two pints of beer a day to be safe of ill affects of alcohol, the committee members seem less conservative. They warn that daily consumption of half a bottle of spirits or eight pints of beer creates "a very considerable risk of acquiring dependence, and this statement should not be taken as meaning that lower levels are necessarily safe." They estimate that two bottles of wine daily may put a pregnant woman into the danger zone for having a child with the fetal alcohol syndrome. They say that four pints of beer daily or "four doubles of spirits" or a bottle of wine "constitute reasonable guidelines for the upper limit of drinking." Although convincing data are lacking on this subject, a report like this intended for the public might have been wiser to have stayed with "Dr. Anstie's limits."

The general statements about treatment efficacy suggest that about 30% of alcoholics will be abstinent a year after intervention, 30% will be less impaired but still drinking, and 40% will be unchanged. This closely parallels the "one-third rule" usually found in follow-up studies in the United States. The committee has the same treatment controversies we do: inpatient versus outpatient, intensive versus minimal treatment, generalist versus specialist, abstinence versus "return to normal drinking," psychotherapy versus behavioral therapy, and so forth.

The recommendations made are sound—primarily that public awareness be greatly increased so that social expectations about alcohol consumption will change. The committee believes that a drop (or at least no further rise) in per capita consumption is an important preventive strategy, something being debated in the United States. They oppose relaxation of license controls and advocate better coordination among government agencies that have some involvement with alcohol and health. They suggest that liquor advertising should be studied and perhaps curtailed, that industry and business should reduce pressures on employees that encourage drinking, and that health professionals should be better educated about alcoholism.

This interesting report is well thought out and clearly written. It is to be hoped it has a beneficial impact on the citizens of England and Wales.

Drug and Alcohol Abuse: A Clinical Guide to Diagnosis and Treatment, *by Marc A. Schuckit, M.D. New York, N.Y., Plenum Medical Book Co., 1979, 193 pp., $16.95.*

It must take a great deal of courage to write yet another book on the diagnosis and treatment of drug and alcohol abuse. In the past two decades we have seen innumerable texts on the subject written from every possible perspective. Some have been good, some bad, and many have been mediocre. The current volume tends toward the good end of the spectrum.

Dr. Schuckit has produced a concise, well-organized, and readable volume. It admirably fulfills his two-fold goal of presenting a volume that can serve as a broad overview of

the common drugs of abuse (including alcohol) as well as providing rapidly accessible data on emergency treatment procedures. Superfluous material is virtually nonexistent. One gets a lot of meat and very little fat. Appropriately selected references can guide the motivated student toward greater depth of knowledge in any area of interest.

The author should also be commended for including problems of alcohol abuse along with other substance abuse. The current tendency to treat alcohol abuse as though it were an entirely separate disease or illness from that of other drug abuse is more political than scientific. A single handbook that comfortably treats the spectrum of drugs of abuse is valuable.

Each chapter treats a major category or class of drugs with abuse potential. Within each chapter sections on pharmacology, epidemiology, and diagnosis are followed by a discussion of emergency problems and treatment characteristic of that class. Special chapters on multi-drug use, over-the-counter drugs, and rehabilitation add breadth and depth to the book. Of special interest to the practicing physician is the well-written chapter on "Emergency Problems: A Rapid Overview," which establishes a logical framework for rapid clinical assessment of drug intoxication when the nature of the drug taken is unknown.

I have a few carping criticisms. The author's definitions of drugs of abuse and of drug abuse are unsophisticated. Part of the problem, of course, lies in the fact that it is not just the pharmacology of the drug that makes it a drug of abuse but, rather, human behavior. The social and psychosocial patterns of use produce abuse. The permutations and combinations of possible behavior patterns and pharmacological interreactions are so numerous as to virtually negate any possibility of clear, concise, and meaningful general definitions.

It is disturbing that the author made no attempt to tie his work into the definitional framework of either *DSM-III* or *ICD-9-CM*. The addition of one or another of these classification systems (they are for all intents and purposes virtually identical) would have added a useful dimension to an otherwise excellent volume.

In summary, this book should appeal to a wide audience. Physicians and others involved in the treatment of abusers—especially in emergency or crises settings—will find it an eminently practical tool.

Handbook of Child and Adolescent Psychiatric Emergencies, *by Gordon K. Farley, M.D., Lloyd O. Eckhardt, M.D., and Frederick B. Hebert, M.D. Garden City, N.Y., Medical Examination Publishing Co. (Excerpta Medica), 1979, 185 pp., $12.00 (paper).*

This handbook is designed to provide mental health workers with help when confronting a child psychiatric emergency. The first three sections of the book are extremely brief, exhorting the clinician to see the opportunities and pitfalls involved when a child is seen under emergency conditions. In addition, they provide a comprehensive outline of a child psychiatric assessment.

The fourth section constitutes almost the entire body of the book. It is titled "Specific Child Psychiatric Emergencies." Since only a few situations in child psychiatry are truly emergencies, this section is in fact an abbreviated textbook of child, adolescent, and (in some cases) adult psychiatry. It discusses acute drug abuse, adolescent schizophrenia, anorexia nervosa, child abuse, and childhood psychoses. By summarizing many classical articles in one place, this section was useful to me as a succinct review of a large body of material, highlighting and refreshing my memory on many details in the assessment and treatment of numerous psychopathological conditions. In that context, the absence of new ideas or of inspired writing seemed less bothersome.

As a handbook of child psychiatric emergencies, the text does not distinguish true emergency situations from those which are less so. The alphabetic arrangement of material contributes to this. It might have been useful to organize the true emergency situations into one brief chapter.

There is a spotty quality to this book: some of its sections are exceedingly well done, including those on runaway children and school phobias, while others, including that on adolescent schizophrenia, represent a simple abridging of sections of the *Comprehensive Textbook of Psychiatry* (1). While this does not detract from the book's useful nature as a refresher, it does highlight the fact that the text could have done more.

After the long section on specific disorders of childhood, the section on psychopharmacology seems repetitious. It could be useful to a clinician who wants to look up a dosage or a particular pharmacologic treatment for child psychiatric conditions. However, I found it the least useful part of the book; it would have been better if it had been more tightly integrated into the previous section.

In conclusion, the *Handbook of Child and Adolescent Psychiatric Emergencies* represents a useful review of, in some cases, overview of child and adolescent psychiatry, with a particular emphasis on more or less acute situations and the emergency situations that sometimes arise from them. The book refreshed my memory, organized a vast body of material into a useful summarized whole, selecting only those pieces of work the authors felt were most pertinent. On the whole, I think the book is a succinct and useful addition to existing literature in this field.

The Psychobiology of the Depressive Disorders: Implications for the Effects of Stress, *edited by Richard A. Depue. New York, N.Y., Academic Press (Harcourt Brace Jovanovich), 1979, 437 pp., $29.50.*

This is a delightful volume that reviews the recent advances in genetic and biological aspects of affective disorders and recent research in life events and points toward areas where knowledge from these disciplines interface. The major thesis involves the concept of vulnerability to disease, a concept that focuses on environmental-biological interactions in the genesis of psychiatric disorders.

The volume has five major sections. The conceptual over-

view of stress and disease presents the major thesis. The second section consists of four chapters, three dealing with classification of depression and one presenting an overview of issues in measurement of stressful life events. The review of unipolar-bipolar distinctions is excellent; it proposes a thoughtful classification based on this dichotomy. A chapter on the endogenous-neurotic distinction is quite comprehensive and well referenced and discusses the effects of antidepressant medication and ECT. The relation of anxiety to depressive states has an excellent review of this topic, and the chapter on measurement of stressful life events presents a format for issues that are elaborated on in subsequent chapters.

The third section discusses the interaction of stress and biological variables in depression. The five chapters in this section concern norepinephrine metabolism in animals and in depressed patients. Neuroendocrine studies in depression, with emphasis on cortisol, are reviewed with regard to diagnosis, catecholamine metabolism, and stress. The chapter on genetic influences on catecholamine metabolism is concerned for the most part with animal studies, although the family studies of catecholamine metabolizing enzymes are covered. The relationships of neurophysiology to stress and depression are discussed.

The fourth section reviews psychosocial aspects of stress and depression. The six chapters in this section discuss studies of life events and depression with emphasis on the studies done in New Haven and London. Psychological theories of depression (reinforcement, self-esteem, and learned helplessness) are discussed in separate chapters. This section concludes with a chapter reviewing cognitive and behavioral factors in the regulation of stress.

The fifth section consists of two chapters that present models for integrating stress-biology interactions. Strategies for future research in depression, including studying children of depressive parents, are discussed.

Although this is a multiauthored volume, the editor has created a good sense of continuity from chapter to chapter and from section to section. The chapters are usually reviews and overviews of topical areas, and particular research studies are often highlighted. Each chapter is well referenced, although for the most part the references are only through 1977.

One problem with any recent book on depression is how to integrate previous studies with the new *DSM-III* nomenclature. *DSM-III* is not addressed in this volume. However, the topics covered are basic to our understanding of psychopathology and provide a useful background as clinicians become familiar with *DSM-III*. This book has considerable information and should be of value to both researchers in depression and clinicians who wish to review recent advances in depression research.

Malpractice: A Guide for Mental Health Professionals, *by Ronald Jay Cohen. New York, N.Y., Free Press (Macmillan Publishing Co.), 1979, 320 pp., $13.95.*

This is an ambitious book by a legal amateur (the author is a psychologist). Although I am an adherent to the maxim that the law is too important to be left entirely to lawyers, I would observe that there are limits to the strictly legal contributions that nonlawyers can make in the law-behavioral sciences dichotomy. A glaring example of the legal naiveté of the author is the statement on page 48, "Whereas criminal cases must be tried by a jury, civil cases can be tried by a jury or judge." Criminal cases of course are regularly tried by a judge when the jury is waived.

There are repeated disclaimers that the book is authoritative, such as, "None of the case material should be construed as constituting a definitive statement of the law." One hundred eight pages are devoted to "vignettes" of illustrative cases. The author indicates that some of these cases are "sketchy." In many, in my opinion, they are worse than that—"simplistic," "distorted," and "irrelevant" are adjectives that occurred to me as I reviewed them. I do not understand, for example, what *In Re Gault* has to do with malpractice.

The author is to be applauded for the enormous and difficult undertaking this book must have entailed. The subject is thorny and complex and does not lend itself to easy generalizations. Quite the opposite: case law in this area is diverse, inconsistent, and often quite idiosyncratic.

I do not mean to convey the message that this book is without *any* merit. The mental health professional who is experienced in the workings of the legal system will learn from this book, indeed will learn a great deal. However, the book should be read with a healthy application of skepticism, given its lack of legal authority, which the author himself acknowledges. If you should get caught up in a malpractice action, the book will help you to understand the complexity of the area, but it is no substitute (nor is it intended to be) for either your insurance carrier or yourself getting the best malpractice lawyer you can find.

East Meadow, N.Y.

Three Millennia of Chinese Psychiatry, *by John J. Kao, M.D. New York, N.Y., Institute for Advanced Research in Asian Science and Medicine, 1979, 179 pp., $10.00 (paper).*

The title of this monograph, which was first written as an M.D. thesis at Yale School of Medicine, appears to be misleading in that there is very little that we would find at all familiar until the beginnings of "missionary psychiatry" in the late 1800s. The meat of this book is an account of the author's observations on a trip to the People's Republic of China in 1973, which has been set in historical context.

Although I found the philosophical ideas of the initial section rather difficult to follow, once Dr. Kao starts describing the early beginnings of modern psychiatry, he becomes a lucid, thoughtful, and careful analyst of trends and events in the development of psychiatric knowledge and practice in China. The descriptions of the neglect and cruelty expressed toward the mentally ill are reminiscent of conditions in the United States and Europe before the advent of Dorothea Dix, Pinel, and others who made attempts to develop humane treatment methods. The historical material is plentifully documented through citation of sources. The account of the John Kerr Refuge for the Insane in Canton, of which I had not previously heard, was compelling and fascinating, a monograph within a monograph and worthy of separate publication.

In spite of these early efforts, only a minuscule portion of the total mental health problem in China was attacked until "after the liberation" in 1949, when the new government decided to devote resources to the study and development of psychiatry. As Dr. Kao points out, psychiatric services were part of a plan to provide general medical care in China, where almost none had previously existed, and prodigious efforts were made to train staff and obtain supplies. By edict, modern and traditional forms of medical care were combined and the best taken from each. An important underpinning of the new psychiatric therapy was political—the concept of the illness as the enemy and the enlisting of the efforts of the patient and his peers in defeating it. The cure thus lay within the individual.

Psychiatry and its patients also changed as ancient scourges were overcome and as a social system was developed that met the basic needs of people within a traditional Chinese framework. For example, mental disease due to syphilis disappeared as prostitution and venereal disease were practically eliminated; senile dementia responded to changes that gave the elderly useful roles and continuing relationships with their families.

Unfortunately, Dr. Kao's account does not cover the past seven years in China since his visit, nor does it attempt to review the more modern literature. For example, the thoughts of Chairman Mao are no longer regarded as therapeutic, and "the little red book" no longer accompanies the patient to the group therapy session. Since the Cultural Revolution, which was ending about the time of Dr. Kao's visit, there has been a substantial increase in the valuing of "progress" as defined in Western terms. Intellectuals are no longer expected to submerge their interests and blend with the peasants, with the consequent loss of scientific contributions and energy that might be more productively spent in the arena for which one was trained. When Dr. Kao wrote he was well aware that changes were continuing and inevitable, and one hopes that he will have an opportunity to share updated information.

All in all, this is an impressive piece of work, with much interesting detail, thoughtfully analyzed and documented. It would be of particular interest to those who wish to know more about the broader implications of the medical and psychiatric social-community care system that has evolved in China.

JOHN S. VISHER, M.D.
Palo Alto, Calif.

The Later Papers of Sir Aubrey Lewis, LL.D., D.Sc., M.D. *New York, N.Y., Oxford University Press, 1979, 245 pp., $37.50.*

This book contains 24 papers written by Dr. Aubrey Lewis between the time of his retirement in 1966 and his death in 1975. The author's predominant orientation is historical and descriptive. He traces the historical development of the definitions and classifications of several mental syndromes from the time of the early Greeks to the present. For example, he lucidly traces the historical development of the concepts of such mental syndromes as anxiety, hysteria, paranoia, phobia, and the psychopathic personality. In each of these instances he reviews the varying use of the terms representing these concepts over time in each of several languages. From these data, using his own observations, he attempts through logical arguments to establish a preferred meaning for each term within the general classification of mental disorders. His arguments are cogent and stimulate one to think about the obvious nosological problems in psychiatry, such as the fact that different psychiatrists include differing patients in the same diagnostic category.

Dr. Lewis' paper on hysterias and his paper on phobias are both very succinct historical critiques of the development of these diagnostic syndromes. In three other papers he 1) traces the historical development of the concept of the endogenous-exogenous dichotomy, 2) shows the cultural relativity of the attitude that drug dependence is damaging, and 3) discusses the reciprocal influence of culture on mental disease and of mental disease (and psychiatry) on culture. Some of the 24 papers are concisely written reviews of books by various authors.

In his various papers Sir Lewis poignantly criticizes and puts into his own perspective many of the different psychiatric approaches. In separate papers he critically evaluates the behavioral, the biochemical, and the psychoanalytic points of view. Although at times he fails to state Freud's views correctly, at other times his criticisms of psychoanalysis are apt. In reviewing current drug research he puts it into perspective by comparing and contrasting it with earlier work on general paresis and ECT.

Although Dr. Lewis tends to critically evaluate the ideas and work of others, rather than put forth new ideas or observations of his own, his clear arguments and the breadth of his historical perspective are enjoyable and informative.

FELIX F. LOEB, JR., M.D.
La Jolla, Calif.

Des Fous dans la Ville? Gheel (Belgique) et Sa Thérapie Séculaire, *by Eugeen Roosens; translated by Maddy Buysee, Jacques Dumont, and Eugeen Roosens. Paris, France, Presses Universitaires de France, 1979, 207 pp., no price listed (paper).*

Virtually no psychiatrist is unaffected by the baffling circumstances of Gheel, the Belgian town that for centuries has provided family care for the mentally ill. Many reports of visits to Gheel are available in the literature from the early nineteenth century, when psychiatry acquired the status of an independent branch of medicine. However, these reports have been anecdotal and have tended to raise rather than to answer questions. Therefore, a monograph on Gheel by a Belgian sociologist in a language accessible to many is certainly welcome. A reading of this work clarifies many aspects of the family care provided for the mentally ill at Gheel, but it still leaves many areas obscure.

First of all, the title of the book is slightly misleading. The reference to Gheel's "centuries-old therapy" may lead readers to believe that this is a historical study. "Centuries-old therapy" is used here in the sense of traditional therapy as opposed to what is used currently. Only a few passages scattered here and there refer to the history of Gheel and the bibliography contains almost no historical references. The tradition of Gheel can be traced as far back as 1250, when the mentally ill were brought to Gheel imploring to be healed at the shrine of St. Dymphna, the Irish princess who, attempting to escape from the incestuous advances of her father, ran

away to Gheel, where her father eventually found and killed her. Although the religious emphasis decreased during the French revolution, the number of mentally ill in Gheel increased up until World War II: there were 200 patients around 1800, 400 in 1820, 900 in 1850 (following the closing of the mental hospital of Brussels), 2,000 in 1900, and 3,736 in 1938.

There are now 1,363 patients at Gheel; they are placed in 1,007 foster families (of which 356 have 2 patients, always of the same sex). Two-thirds of the patients are male, one-third are female; 45% are 55 years old and older; one-third are diagnosed as schizophrenic and tend to be withdrawn, and two-thirds are diagnosed as oligophrenic; they are placed in 10 different districts, each staffed by nurses who are always available and who work for the "Etablissement" (the Center for Family Care). This program has been run by the state since the second half of the nineteenth century, and the religious influence is minimal (even the annual procession for St. Dymphna was discontinued 15 years ago). Roughly half of the families who care for patients are rural and half are urban; they are all lower-class families. Their motivation to accept patients is economic rather than charitable. Although in the past there were many instances of exploitation of mental patients by families, this is apparently no longer the case.

The author of this book, a professor of sociology at the Catholic University of Louvain, focuses his study on the life of patients outside the context of the foster family. Toward the end of the book he reports that most of the patients in family care tend to be submissive the first three months, rather rebellious the next three months, and then to develop a more cooperative attitude. Thus the patient's "sick" image is eventually replaced by a "healthy" image.

Most of the chapters of the book deal with the result of a questionnaire distributed to the foster families and with direct observation by some of the author's students. The researchers found that most of the patients are free to walk outside on their own and to receive relatives, although 52% have no visitors at all. Most of the patients are indistinguishable from the other citizens when they are in public. This is in contrast to the past, when patients had to wear uniforms. Criminal behavior and sexual acting out among the patients are virtually nonexistent. The patients can attend movies for children on Sundays, and they spend long hours at the "cafe," which is similar to but not entirely like an American bar; a good part of the leisure time of the villagers evolves around the cafe. The patients are not served liquor there, at least not officially, and their behavior is tolerated through a condescending attitude and a network of community supervision. On the whole, life in Gheel—a town of 30,000 inhabitants—is not very eventful, in spite of the presence of the mental patients.

Should a patient become unmanageable, he or she is immediately taken care of by the nurse of the Etablissement. In fact, the worst fear of the patients is to be returned to the hospital. This happens only in rare instances (i.e., 22 cases in 1976), which is truly remarkable in view of the severe psychotic symptoms of many of the patients (several instances of these are reported in the book) and in view of the limited use of psychopharmacological agents. The book's findings indicate that most of the foster families are skeptical about medications and tend to view the disorder of their foster patients as organic; they do not consider dynamic and interpersonal factors. These families have a clear-cut perception of normal and abnormal behavior (which explains why the patients are never accepted as members of religious congregations) and emphasize the healthy aspects of the patients' personality—in fact, their boarders are never called "patients"; they are called "pensionnaires."

The reader may have many questions, such as, Is the system of care at Gheel unique because of the tradition? If not, could it be repeated somewhere else? How much of its success is due to the social stability of the population—both the foster families and the patients—which is at variance with the instability of the nuclear family of the highly industrialized nations, notably the United States? How does this system compare with similar ones recently instituted in developing countries, notably Africa? How do the results compare with other systems of family care elsewhere?

Much more research is needed to obtain even a partial answer to these and to many other questions, but it is refreshing to see that the obscurity that surrounded the Gheel system has been somewhat clarified. It is notable that this has been accomplished through the Gheel Family Care Research Project sponsored by Leo Srole, an American sociologist, with the support of Columbia University. A historical study of the Gheel system would be even more difficult to accomplish. The present volume may at least encourage others to continue to study this unique system, which anticipated by centuries today's concern with placing mental patients back in the community.

Psychiatric Aspects of Minimal Brain Dysfunction in Adults, *edited by Leopold Bellak, M.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1979, 202 pp., $19.50.*

This is the edited volume of a conference on adult minimal brain dysfunction that was held in the spring of 1978. The conference participants are outstanding clinicians and researchers in this area. Specifically, the 18 contributors present a series of major papers that review the areas of definition, diagnostic aspects, treatment and management (including follow-up studies), family dimensions, and relationships to allied disorders (e.g., sociopathy and schizophrenia).

The book is arranged into four sections. The first section is a splendid overview of the concept of adult minimal brain dysfunction by the chairperson of the conference and editor of this volume (Dr. Bellak). This is followed by an outstanding review of the nomenclaturial and clinical-diagnostic issues involved by Dr. Paul Wender. The second section, titled Follow-Up and Family Studies, explores the clinical manifestations of this syndrome with particular reference to long-term studies and family trends, including an excellent follow-up study by Dr. Barry Borland of the social-behavioral adaptation of adults who had been viewed as hyperkinetic boys. The general discussion of this section by Dr. Jonathan Cole sets a high standard for the similar discussions that follow. The general discussion focuses on correlations to allied disorders and unanswered questions. All in all, it provides a wealth of clinical reflections that make the book clinically relevant.

The third section of the book, Neuropsychiatric Aspects, reviews ego functions in adults with minimal brain dysfunction, possible relationships to epilepsy and/or episodic ag-

gressive behaviors, sensory motor disturbances, and clinical correlates of cerebral dysrhythmias in individuals who had adult minimal brain disorder who later develop such disorders as schizophrenia. The last section, Therapeutic Aspects, includes two superb presentations of a kind rarely seen in a book of this nature. First, there is a refreshing review by Dr. Stanley Greenspan of psychotherapeutic potentials for individuals with this disorder. This is in contrast to the usual focus on psychoactive medication in treatment and management. In particular, this presentation takes a hard look at the developmental, intrapersonal, interpersonal-family dynamics, and "at risk" neurophysiological dimensions and correlates these in a meaningful approach to management. Similarly, Dr. L. Eugene Arnold's contribution, titled "Philosophy and Strategy of Medicating Adults with Minimal Brain Dysfunction," provides a number of excellent visual illustrations that clearly elaborate the key symptoms of adult minimal brain disorder as well as outline equally clear treatment guidelines for managing the syndrome. Particular reference is made to therapeutic-management considerations; the emphasis is on the fact that medication should not be abused, misused, or used as a crutch or "cure-all" for this complex disorder.

This is the only high-quality extended discussion of adult minimal brain disorder available in the psychiatric literature. It is presented in excellent depth, incorporates a wide-based approach to current knowledge and viewpoints, and, because of the consistent excellence of the formal-informal general discussions that accompany each major section of the book, there is a coherent wholeness to this volume that is rarely seen in edited endeavors.

In summary, this is an excellent volume for all those who are interested in specific developmental issues in psychiatry, child psychiatry, interrelationships of early childhood disorders to later adult maladaptive behaviors, and the perplexing issues of etiological determinants to the adult character disorders and major psychoses. The format of presentation is a model of clarity. I recommend it highly.

FRANK J. MENOLASCINO, M.D.
Omaha, Neb.

Brain and Mind. Ciba Foundation Symposium 69. *Amsterdam, the Netherlands, Excerpta Medica, 1979, 413 pp., $51.25.*

For those who are beguiled by the elusive problem of dualism, the title of this volume seems like an invitation to a feast. The student interested in the subject often becomes impatient with a priori philosophical speculation. There seems to be no way to unravel the mind/body distinction through finer verbal shadings. Many of us who come at the problem as psychological or social scientists see mind (as opposed to body or brain) as composed of a series of intervening variables, that is, as promisory notes to be paid off in the study of brain chemistry, physiology, and even, ultimately, physics. For others of us, myself included, psychological understanding is simply a separate framework, *complementary* to the "more objective" study of physiology, chemistry, and physics. The study of social sciences is a different way of viewing the same phenomena viewed by the hard scientist. An analogy might be drawn to a painting. The pigment chemist can describe the ingredients on the canvas: the amount of titanium, lead, cobalt, etc., present. Yet the painting, aesthetically, is a phenomenon unto itself, to be perceived artistically. Its meaning, in the framework separate from the objectively established one of the chemist, is mostly within the viewer, but it would not exist without its physics, the chemistry of physical structure.

Complementarity becomes a possible alternative to either/or approaches to important human experience. This complementarity justifies a dualism while accepting holism (the experience of the painting could not exist without its physical elements), yet it integrates both.

What is nice about this volume is that the physiologist attends to the philosophical problem as well as "doing his own thing." In that particular regard this book gives us nearly a full measure. A range of subjects is challenged, and a refreshing assortment of insights and facts on some new work can be gained. There is even a subject index at the end of this book, for which the editors are to be congratulated; very often published symposia omit that kindness.

The general format of the book is to present two papers on a particular subject followed by commentary by a third person and a general discussion. The subjects covered are the evolutionary aspects of the brain, language, perception and memory, consciousness, experimental surgery and clinical neurology, pain and the senses, psychosis and abnormal behavior, pain and mood, and triunism. Throughout there is a serious attempt at clarity (for which I, reluctantly, give the scientists higher grades than the philosophers) as well as an attempt to meet the challenge of the antiquity and profundity of the problem. I especially liked the essay titled "Language: Perspectives from Another Modality" by Ursula Bellugi and Edward Klema, an essay on American sign language. (As a small example of a bit of interesting information: right-handed native deaf signers have better processing of signs in the left hemisphere than the right, although spatial-temporal function is usually assumed to be more a right-brain function than a left-brain function.)

Another essay of interest to me is the one by Creutzfeldt on "Neurophysiological Mechanisms and Consciousness." Creutzfeldt introduces the term "reflective loop" to express the way in which the brain symbolically presents the world to itself and then reflects on that particular representation. This is guessed to be the basis of the dualistic experience of ourselves and the world and the basis of our phenomenology.

Other portions of this volume will interest both specialists and those with a broader interest in the subject. The book does not resolve the mind/body dilemma totally; it does, however, present both facts and ideas that make the ambiguity more tolerable. The people at Ciba are to be congratulated for this book.

Work and the Family System: A Naturalistic Study of Working-Class and Lower-Middle-Class Families, *by Chaya S. Piotrkowski. New York, N.Y., Free Press (Macmillan Publishing Co.), 1979, 331 pp., $14.95.*

Thirty members of 13 working-class and lower-middle-class families from one midwest and one far west state participated in this study. Two of the families were observed at

work and at home for about 18 hours each. The other families averaged 3.5 hours of interviews.

Although this was a study of work and the family system, most interviews seemed dyadic—interviewer and single interviewee. I wonder what a family systems approach to the interviewing, involving the whole family, would reveal.

There is ample case history documentation of work as alienating to the family and family life, yet no other system is proposed. To work and to love may still have to be compartmentalized and separate.

The main impact this book had on me was to emphasize the psychosocial factors involving work and the family. This underlines the changing medical model of disease as exemplified in the work of George Engel's biopsychosocial model (1). In addition to symptoms, signs, and laboratory findings, this model carefully assesses the role of stress, family, work, the treating physicians, the health care system, and other variables in the person and his illness.

There are few surprises in this book, and I suspect that it will not be of much interest to clinicians. It may interest family researchers.

ROSS V. SPECK, M.D.
Philadelphia, Pa.

Child Psychiatry in Asean Countries: A Book of Readings, *compiled by William M. Bolman, M.D., and Thomas W. Maretzki, Ph.D., for the ASEAN Child Psychiatry Forum. Quezon City Philippines, New Day Publishers (Detroit, Mich., Cellar Book Shop, distributor), 1979, 180 pp., $8.25 (paper).*

This volume is a compilation of papers selected from those presented at a workshop on child and adolescent psychiatry held in Djakarta, Indonesia, and at the World Psychiatric Conference in Honolulu, Hawaii, in 1977. The book is divided into three parts in which 18 authors present their views on the Status of Child Psychiatry in Each Asean Country, Cross-Cultural Issues in Child Psychiatry in Asean Settings, and General Issues for Cross-Cultural Psychiatry.

The five chapters in part one are devoted to the status of child psychiatry in Indonesia, Malaysia, the Philippines, Singapore, and Thailand. Imagine what it would be like to be one of a handful of child psychiatrists for a population of more than 135,000,000 people, of whom approximately 40% are minors, representing 300 ethnic subgroups, 250 different languages, the major religions of Islam, Christianity, and Hinduism in addition to indigenous belief systems, and spread over 5,500 km of islands and ocean! Dr. Yan Prasetyo briefly describes such a practice in Indonesia.

Part two of the text is a potpourri of diverse papers on everything from child rearing in Java to the reculturation shock of returning professionals. Underlying these chapters are issues surrounding the imposition of Western concepts of treatment, pathology, and child development on the native population. This is specifically salient when Dr. Quintos informs us, for example, of the Filipino transgenerational advice, "Sleep with your children so that they will grow close to you." This, coupled with the extended family kinship patterns, makes one look at child developmental issues in a less ethnocentric manner.

Part three deals with the more general impact of culture on the practice of child psychiatry. Dr. Bolman's essay on urbanization debunks a commonly held belief that urbanization is dangerous to people in terms of their mental health as they shift from peasant-rural life to modern industrial life. He believes that what is dangerous is a type of experience people encounter in the transition from village to city, and he feels that urbanization in developing nations must provide "social structures or institutions that will be able to offer support and a sense of belonging and cultural continuity." He then goes on to provide several recommendations for the development of child and family mental health services. One proposal, for a preventively oriented integrated community service, is a "community information center that would serve as the psychological and social equivalent to the biomedical services of the public health center." Dr. Bolman also suggests "the creation of a network of community family life centers." These centers would be primarily day-care services for children that would allow the children to make the transition from the extended family network of rural life to the increased social responsibility and independence necessary for urbanized nuclear family living.

In sum, aside from some irritating misspellings, typographical errors, and the absence of an index, this collection of readings offers the practitioner a sobering mirror to his or her own professional ethnocentricities and may be a useful resource book in confronting the increasingly complex issue of providing child psychiatric services for the Indo-Chinese refugees coming to the United States, who are in many ways similarly dislocated in both cultural and urban life.

Stopping Wife Abuse: A Guide to the Emotional, Psychological, and Legal Implications, *by Jennifer Baker Fleming. Garden City, N.Y., Anchor Books (Anchor Press/Doubleday), 1979, 516 pp., $8.95 (paper).*

"What this book is designed to do is to provide you with the insight, information, skills and knowledge you need if you are contemplating or are providing help to battered women," writes the author. As a psychiatrist who has a basic psychoanalytic understanding of the motivation for all human behavior but who has an eclectic approach to the resolution of the conflicts produced by the many factors involved in effecting that behavior, I think this book fulfills its goal primarily in providing valuable information about the legal systems, legislation, current research, and programs providing services to battered women. Interwoven throughout the book are statistics and information that help the reader realize the magnitude and scope of domestic violence, its historical roots, and the overwhelming task of attempting to prevent it. There is much good practical "how to" advice for friends and relatives, the legal and criminal justice system, mental health practitioners, children, and husbands in helping the "victim."

I think that by referring to the battered woman as the "victim" the author has done her a disservice and has compounded the anger of the assaulter. Negating the fact that a

woman *shares* in the responsibility for what happens to her and not helping her see that her reactions at a critical point in an angry exchange more often than not trigger the violent behavior contribute to the list of reasons why so many men are turned off by professional help.

Both men and women are influenced by the effects of their biological differences, parental conditioning, and societal stereotyping. Both are victimized by the intolerance bred by the lack of understanding of unconscious roots of human behavior. I agree that each may need some geographic and psychological private space following a violent outburst, but unless the participants can be helped to see that they must ultimately work together in finding the external factors, interpersonal forces, and intrapsychic forces contributing to the conflict, both will experience a sense of failure should the relationship not survive. The single most pressing goal of most people who seek professional help is to be able to establish and maintain a meaningful one-to-one relationship.

I believe that by not differentiating between counseling and psychotherapy, not understanding the levels of psychotherapy, ignoring the unconscious factors that motivate human behavior, and minimizing the medical role, the author removes the psychiatrist from the team needed to provide a full range of services. The psychiatrist could be a valuable member of that team.

Not only the author is responsible for contributing to the lack of insight and knowledge by negating the overwhelming unconscious forces that sabotage so many of the more superficial efforts, but so is the psychiatrist for not becoming more involved outside the "office." The lack of clarity as to what constitutes psychotherapy, the difference between emotional disturbance and mental illness, and the minimal role of the physician helper are the responsibility of the psychiatrist, who by his or her absence allows this oversight to be perpetuated to the detriment of those who desperately need help.

Currents in Alcoholism, Vol. 6: Treatment and Rehabilitation and Epidemiology, *edited by Marc Galanter, M.D. New York, N.Y., Grune & Stratton, 1979, 332 pp., $33.50.*

The thought occurred to me while reading this book that the great papers in the field of alcoholism have already been written and the great thoughts already expressed. However, people working in the area need a reason to get together. Few of the 26 papers in this volume have abstracts, and in too many cases the knowledge to be extracted from the abundance of charts, graphs, and tables is not worth the effort. There are six sections: 1) The Alcoholic in the General Hospital, 2) Ambulatory Treatment, 3) Outcome, 4) Alcoholism in Women, 5) Alcoholism in Adolescents, and 6) The Drinking Driver. Each section has an introductory paper that is itself interesting but does not take the place of an abstract.

Several of the papers concern the apparently ever-nagging problem of diagnosis and with the extent to which the criteria of the National Council on Alcoholism lead to false positives and negatives. A lot of the problem still seems related to the effort to find in the large motley of alcohol abuse a single disease entity.

In one section the point is made that admission to a general hospital very often provides the first opportunity to confront the alcoholic with his or her problem. Later, however, we are told that it is unlikely that many alcoholics would need inpatient care at all if outpatient facilities were adequate; this includes the idea that a great deal more withdrawal from alcohol could be done without using an expensive hospital bed for detoxification.

One paper draws attention to the similarity between religious conversion, cults, and AA, particularly with regard to the "social support network." While the social support network can indeed sustain sobriety, it can also sustain drinking or even sensible alcohol use. Another paper addresses the question of whether the professional and AA can coexist. The answer is yes, but the psychotherapist should leave AA alone, much as he or she leaves the patient's religious beliefs alone.

One study of patients allowed to choose to drink during hospital treatment revealed that on follow-up the abstinent patients did better but that the patients who were drinking moderately by no means underwent rapid, progressive deterioration. This raises again the question as to whether there is not a substantial group of alcohol abusers whom we could help more by offering treatment other than abstinence-oriented programs.

With regard to driving while intoxicated, one author estimated that only 1% of the people who have driven with a blood alcohol concentration of over .05 mg/100 ml have been arrested. Two studies of programs for people who drink and then drive failed to demonstrate that the programs were effective.

The section on women can be summed up quickly: women are drinking more. The percent of women who remain abstinent after treatment is not different from that of men. The daughters of alcoholic fathers drink more, and assertiveness training is a good adjunct to other therapy.

It could be that with AA groups in every small town, detoxification units in every county, halfway houses in every city, programs for alcoholics in every industry, and more strict prosecution of drunk driving we have gone as far as we can go. The only thing left is a major change in lifestyle.

OFFICIAL ACTIONS

Highlights of the 133rd Annual Meeting

The 133rd annual meeting of the American Psychiatric Association, which focused on the theme "To Love and to Work," was held in San Francisco, Calif., May 3-9, 1980. The total registration was 11,428, including 5,858 members and Fellows, 1,530 nonmember professionals, 799 exhibitors, 190 members of the press, and 2,599 spouses and families of members.

The opening session, on Monday morning, May 5, was brought to order by Alan A. Stone, M.D., 108th President of the Association. The invocation was given by the Reverend Toshio Murakami, Director of the National Headquarters of the Buddhist Churches of America, San Francisco. Official greetings were extended by the Honorable Dianne Feinstein, Mayor of San Francisco.

Dr. Stone then introduced distinguished representatives of psychiatric and related organizations from the United States and other countries:

Dr. George Mahy, immediate Past President, Caribbean Psychiatric Association; Dr. Edwin Lipinski, President, Canadian Psychiatric Association; Dr. G.J. Sarwer-Foner, President, Canadian Psychoanalytic Association; Dr. Adib R. Mikhail, representing the Egyptian Psychiatric Association; Dr. Marcel Arditti, representing the French Medico-Psychological Society and General Secretary of the French Association of Psychiatry; Prof. D. Hanfried Helmchen, President, German Association for Psychiatry and Neurology; Dr. C.N. Stefanis, Past President, Greek Society of Neurology and Psychiatry; Dr. C.M. Chung, President, Hong Kong Psychiatric Association; Dr. Shridhar Sharma, representing the Indian Psychiatric Society; Prof. L.S. Gillis, Chairman of the Executive Committee of the Society of Psychiatrists of South Africa; Mr. Gowan T. Guest, President, World Federation for Mental Health; Dr. Tom van der Grintin, General Director, National Institute for Mental Health in the Netherlands; Dr. John Carleton, President, World Association for Social Psychiatry; Dr. John Howells, representing the Royal College of Psychiatrists; Dr. Mauro Villegas, President, Inter-American Council of Psychiatric Associations; Dr. Ayo Binitie, President, Association of Psychiatrists in Nigeria; Dr. Jorge M. Velasco Alzago, representing the Mexican Psychiatric Association; Dr. Robert L. Stubblefield, President, American Academy of Child Psychiatry; Dr. Martin Gershman, Chair, California Chapter, American Academy of Pediatrics; Dr. Nathan T. Sidley, President, American Academy of Psychiatry and the Law; Dr. Paul H. Feldman, President, American Academy of Psychoanalysis; Dr. Joel Yager, President, American Association of Directors of Psychiatric Residency Training; Dr. Mehadin K. Arefeh, President, American Association of Psychiatric Administrators; Dr. Jack C. Westman, President, American Association of Psychiatric Services for Children; Dr. Stanley R. Dean, President, American Association for Social Psychiatry; Dr. Marc Hollender, President, American Board of Psychiatry and Neurology; Dr. Leonard M. Riggs, Jr., President-Elect, American College of Emergency Physicians; Dr. Herbert S. Ripley, President, American College of Psychoanalysts; Dr. Maurice Fox, Regent, American College of Physicians; Dr. Shervert Frazier, President, American College of Psychiatrists; Dr. Lois Skully, immediate Past President, American Medical Women's Association; Ms. Martha Mitchell, Chairperson, Division on Psychiatric and Mental Health Nursing, American Nurses' Association; Dr. Arnold M. Cooper, President, American Psychoanalytic Association; Dr. Nicholas Cummings, immediate Past President, American Psychological Association; Dr. June Jackson Christmas, President, American Public Health Association; Dr. D. Steve Goudelock, President, American Society for Adolescent Psychiatry; Dr. Peter Santucci, President, American Society for Physician Analysts; Dr. Patrick McKegney, President, Association for Academic Psychiatry; Dr. Gerald A. Melchiode, President, Association of Directors of Medical Student Education in Psychiatry; Ms. Julia Robinson, President, Association of Mental Health Administrators; Chaplain Clark S. Aist, President, Association of Mental Health Clergy; Dr. Andrea Delgado, President, Black Psychiatrists of America; Dr. Carolyn B. Robinowitz, Vice President, Council on Medical Specialty Societies; Dr. Robert Gibson, President, Group for Advancement of Psychiatry and Past President of the American Psychiatric Association; Mr. Allen R. Moltzen, Trustee, the Mental Health Association, Ms. Barbara A. Graham, member, Board of Directors, National Association of Social Workers; Mr. Donald Fox, President, National Council of Community Mental Health Centers; Dr. Vertis Thompson, President-Elect, National Medical Association; and Dr. Lewis Robbins, President, National Association of Private Psychiatric Hospitals and Vice-President of the American Psychiatric Association.

Dr. Stone also recognized the past Presidents and members of the Board of Trustees of the American Psychiatric Association, the past Speakers and members of the Executive Committee of the Assembly, past Vice-Presidents of the Association, District Branch Presidents, newly elected APA officers, newly elected Assembly officers, and the chairpersons of APA Councils.

Dr. Stone then introduced the San Francisco Civic Chorale, who performed the "Hallelujah Chorus" from Handel's *Messiah* under the direction of Ms. Winifred Baker.

Linn A. Campbell, M.D., Chairperson of the Task Force on Arrangements, was introduced by Dr. Stone, who thanked the task force for an imaginative job of arranging the leisure time activities.

Dr. Stone extended the Association's appreciation to Allan Beigel, M.D., and the Program Committee for their excellent work. He then presented a Special Commendation for Service to Dr. Beigel.

Vice-President Peter A. Martin, M.D., introduced Dr. Stone, who gave the Presidential Address, "Conceptual Ambiguity and Morality in Modern Psychiatry." Vice-President Lewis L. Robbins, M.D., then introduced Donald G. Langsley, M.D., who responded as the President-Elect. (The texts of these addresses are published elsewhere in this issue of the *Journal*.)

The opening session closed with a benediction by the Reverend Hannibal Williams of the New Liberated Presbyterian Church in San Francisco, and with organ music by John E. Fryer, M.D. Dr. Stone then adjourned the meeting.

EXTRAORDINARY SESSION

Immediately after the Opening Session a special session was held for discussion of equal rights for women and the Equal Rights Amendment. Dr. Langsley, chairperson of the session, introduced Dr. Stone, who outlined the history of APA's support of the ERA. Presentations were given by Judd Marmor, M.D., and Jean Baker Miller, M.D., and were followed by questions and comments from the floor.

BUSINESS SESSION

The business session was convened as a meeting of the Assembly of District Branches acting for the membership in responding to reports of the officers and actions of the Board of Trustees. The meeting followed the Extraordinary Session in the Arena of the Civic Auditorium. Dr. Stone presided. After a memorial to deceased members and Fellows, John S. Visher, M.D., gave a memorial to past Speaker Dr. Warren S. Williams. H. Keith H. Brodie, M.D., speaking for Edward C. Kirby, M.D., Chairperson of the Committee of Tellers, announced the results of the election of officers and trustees, the vote on amendments to the Constitution and By-Laws, and the vote on the referendum to rescind the Board of Trustees' decision not to hold APA meetings in states that have not ratified the Equal Rights Amendment.

The reports of the officers to the membership followed. (The floor was open to questions after each report, and all reports were accepted as read by the Assembly.) After H. Keith H. Brodie, M.D., presented the Secretary's report, Charles B. Wilkinson, M.D., Treasurer, reported a surplus of income over expenses for 1979 due in part to *DSM-III* sales, continuing education course revenues, a strong grant/contract program, and increases in rate schedules for APA products and services. Robert O. Pasnau, M.D., Speaker of the Assembly, focused on seven major problem areas—money, education, politics, bureaucracy, law, internal organization, and future planning. The Assembly's Speaker-Elect, Melvin M. Lipsett, M.D., urged proactive involvement in legislation, research, and public information. Lawrence Hartmann, M.D., Chairperson, Committee on Constitution and By-Laws, presented 6 amendments to the Constitution and By-Laws. Philip M. Margolis, M.D., Chairperson of the Committee on Membership, reported on discussions at the committee's October meeting on criteria for Fellowship and on continuing medical education requirements. Melvin Sabshin, M.D., presented the report of the Medical Director.

Dr. Stone then presented the Speaker's plaque to Robert O. Pasnau, M.D., retiring Speaker, and the Vice-President's badge to Lewis L. Robbins, M.D., the retiring Vice-President. Judd Marmor, M.D., presented the President's badge to Dr. Stone.

Dr. Stone then adjourned the business session and called the annual forum to order. The membership voted to refer to the Board of Trustees their sentiment favoring not holding annual meetings in states that have not ratified the ERA after the 1981 meeting, until the issue is resolved in the nation. There was also discussion of a variety of problems in the JCAH Consolidated Standards. An amendment regarding continuity of care was referred to the Board. Dr. Stone then adjourned the annual forum.

SCIENTIFIC SESSIONS

The scientific sessions began Monday afternoon, May 5. There were 178 papers presented in regular sessions, as well as 380 papers in symposia. There were 43 issue workshops, 109 evening panels, 29 videotaped sessions, 15 films, and 46 papers on new research. With few exceptions, the official annual meeting program met the criteria for continuing medical education Category I credit, as did the 115 continuing education courses offered throughout the week.

There were 26 special lectures. Jeanne Spurlock, M.D., Deputy Medical Director, Minority Fellowship Program, APA, and Clinical Professor of Psychiatry, George Washington University and Howard University, Washington, D.C., spoke on "The Seventies: Societal Changes and Their Impact on Child Psychiatry." Alan M. Dershowitz, LL.B., gave a lecture titled "Law and Psychiatry: Are They More Comfortable Married, Divorced, or Living Together?" The Honorable Nathan J. Stark, Under Secretary, United States Department of Health, Education, and Welfare, gave a speech titled "The Federal Government's Role in Mental Health in the 1980s." Stanley N. Cohen, M.D., Professor of Medicine and Professor and Chairman, Department of Genetics, Stanford University, spoke on "Gene Manipulation of Microorganisms: Current and Future Prospects." Helen Singer Kaplan, M.D., founder of the Human Sexuality Program, New York Hospital-Cornell Medical Center, spoke on "Current Concepts of Human Sexuality."

The APA's Founders Award Lecture, "Que Sera Sera No Tiene Que Ser (Plan or Perish)," was delivered by Jack R. Ewalt, M.D., Past President of APA and Director, Mental Health and Behavioral Sciences, Department of Medicine and Surgery, Veterans Administration. The writer Michael Crichton, M.D., spoke on "Why Work Is Work." James N. Glick, M.D., an orthopedic surgeon in private practice in San Francisco, gave a speech titled "Sports Injuries: Enjoyment with Pain." The Honorable Harry A. Blackmun, Justice of the Supreme Court, spoke on "Psychiatry and the Supreme Court." The Benjamin Rush Lecture, "Medical Evangelism and Psychiatry: The Case of Psychosomatic Medicine," was presented by Nathan G. Hale, Jr., M.D., Professor of History, University of California, Riverside. James O'Toole, Ph.D., Director, Twenty Year Forecast, and

Associate Professor of Management, University of Southern California, spoke on "Work and Love (But Mainly, Work)." Sherven H. Frazier, M.D., Psychiatrist-in-Chief, McLean Hospital, Belmont, Mass., gave a lecture titled "More Violence: The Wave of the Future?" James L. Bernene, M.D., Associate Clinical Professor of Medicine, Yale University, and Director, Medical Residency Program, Greenwich Hospital, Greenwich, Conn., spoke on "Hypoglycemia, Fact or Fantasy?" "The Working Family: A Researcher's View of Health in the Household" was presented by David Reiss, M.D., Center for Family Research, George Washington University, Washington, D.C. The Seymour Vestermark Memorial Lecture, "The Vestermark Tradition, 1960-1980," was presented by Francis Neil Waldrop, M.D. Helen M. Ranney, M.D., Chairperson, Department of Medicine, University of California, San Diego, spoke on "Advances in Hematology: Changes in the Outlook of Hematologic Disease Over Three Decades." Jack Weinberg, M.D., Director, Illinois State Psychiatric Institute, Chicago, and Professor of Psychiatry, Abraham Lincoln School of Medicine, University of Illinois and Rush Medical College, Rush-Presbyterian-St. Luke's Medical Center, gave a lecture titled "No Synonym for the Word Love."

The Solomon Carter Fuller Lecture, "The Rights of Prisoners and Patients in State Institutions," was given by the Honorable Constance Baker Motley, member of the United States Court of Appeals, Second District (New York). Barbara Ehrenreich, who writes on subjects related to women and health, spoke on "Work and Love: Can Women Have Both? (And Are They Worth It When We Get Them?)" "Headache: Current Concepts" was presented by Neil H. Raskin, M.D., Professor and Vice-Chairman, Department of Neurology, University of California, San Francisco, School of Medicine. The Simon Bolivar Lecture, "Value Systems and Sexual Morality," was delivered by Otto F. Kernberg, M.D., Medical Director, New York Hospital-Cornell Medical Center, Westchester Division; Professor of Psychiatry, Cornell University Medical College; and Training and Supervising Analyst, Columbia University Center for Psychoanalytic Training and Research. Herbert S. Kaufman, M.D., who is an allergist in private practice in San Francisco, gave a lecture titled "TB or Not TB: An Overview of Basic Mechanisms of Man's Immunity." George E. Vaillant, Professor of Psychiatry, Harvard Medical School, spoke on "Erikson's Stage of Industry: A Powerful Predictor of Adult Mental Health." Senator Spark Masayuki Matsunaga spoke on "Mental Health in the '80s: A Senator's View." "The Interface of Brain and Behavior: Temporal Lobe Epilepsy" was presented by Bruce O. Berg, M.D., Professor of Neurology and Pediatrics and Director of Child Neurology, University of California, San Francisco. Silvano Arieti, M.D., Clinical Professor of Psychiatry, New York Medical College, presented a lecture titled "The Family of the Schizophrenic: Re-Valuation of the Psychodynamic Role and Participation in Patients' Rehabilitation."

CONVOCATION

The 24th Convocation of Fellows was held in the Continental Ballroom of the San Francisco Hilton Hotel on Monday evening, May 5, at 7:30 p.m. Dr. Stone presided. After the processional march, Dr. Stone called the convocation to order. The invocation was given by the Reverend Leonidas C. Contos of the Greek Orthodox Church of the Holy Cross, Belmont, Calif. Dr. Langsley introduced the Life Fellows and conducted the induction of Fellows. Dr. Stone then introduced the Life Fellows and Life Members who have been in the Association for 50 years (1930-1980): Grace Baker, M.D., New York, N.Y.; Ralph Warren Bohn, M.D., Lansdowne, Pa.; Leon Joseph Saul, M.D., Media, Pa.; Louis Adrian Schwartz, M.D., Rockport, Mass.; and Jean A. Thompson, M.D., Brandford, Conn. Ms. Evelyn Stone, Belmont, Mass., was designated Honorary Fellow; Semyon Gluzman, M.D., Siberia, U.S.S.R. (in exile), was designated Distinguished Fellow; and Stanislaw Dabrowski, M.D., Warsaw, Poland, Professor Detlev Ploog, Munich, West Germany, Jan Frans Schrijvers, M.D., Geel, Belgium, and Costas N. Stefanis, M.D., Athens, Greece, were designated Corresponding Fellows.

The presentation of awards followed. Dr. Stone presented the Distinguished Service Award—given to APA members "whose distinguished careers have ennobled the profession of psychiatry"—to Daniel Blain, M.D., Past President and former Medical Director of APA, and Seymour S. Kety, M.D., Professor of Psychiatry, Harvard Medical School, and Director of the Laboratories for Psychiatric Research, Mailman Research Center and McLean Hospital.

The Foundations' Fund Prize for Research in Psychiatry, established in 1977 to recognize those who have made distinguished contributions to research in psychiatry, was presented by Herbert Pardes, M.D., to Merton M. Gill, M.D., for "distinguished contribution to psychoanalytic theory and to the systematic study of the psychotherapeutic process," to Mardi J. Horowitz, M.D., for "distinguished contribution to an understanding of the psychological processes following serious life events and of the adaptive changes facilitated by psychotherapy," and to Albert J. Stunkard, M.D., for "distinguished contribution to an understanding of eating disorders and the development of research methodology in this and cognate areas."

The Blanche F. Ittleson Prize for Research in Child Psychiatry, established in 1977 to "honor outstanding research in child psychiatry, in particular as it relates to the mental health of children," was presented by Reginald Lourie, M.D., to Stella Chess, M.D., Professor of Child Psychiatry, Department of Psychiatry, New York University Medical Center, and Alexander Thomas, M.D., Professor, Department of Psychiatry, New York University School of Medicine and Attending Psychiatrist, Bellevue Psychiatric Hospital.

Irving Philips, M.D., presented the Agnes Purcell McGavin Award to Albert J. Solnit, M.D., Director, Child Study Center, and Sterling Professor of Pediatrics and Psychiatry at Yale University School of Medicine, for his "outstanding contributions to the prevention of mental disorders in children."

The Isaac Ray Award was presented by Jonas Robitscher, M.D., to Seymour L. Halleck, M.D., Professor, Department of Psychiatry, Associate Director for Recruitment, Residency Training, and Adjunct Professor, University of North Carolina Law School, Chapel Hill, N.C., for his "outstanding contributions to legal psychiatry."

The Seymour D. Vestermark Award was presented by Herbert Pardes, M.D., to Francis N. Waldrop, M.D., recently retired from a career in training and education with Saint Elizabeths Hospital, the National Institute of Mental Health, and the Alcohol, Drug Abuse, and Mental Health

Administration, for "outstanding contributions to undergraduate and postgraduate medical education, to continuing education, and to the education of behavioral scientists for research."

The APA Founders Award, established in 1976 to "honor members of the Association who have made outstanding contributions as author, spokesperson, and advocate in the service of the mentally ill and disabled and to the art and science of helping them," was presented by Shervert H. Frazier, M.D., to Jack R. Ewalt, M.D., Director, Mental Health and Behavioral Sciences, Department of Medicine and Surgery, Veterans Administration, Washington, D.C., and Past President of APA, for "the landmark document, 'Action for Mental Health,' which resulted from the work of the Joint Commission on Mental Illness and Health."

Dr. Frazier also presented the Robert T. Morse Writers Award to Mr. Darrell Sifford, columnist for *The Philadelphia Inquirer,* and the District Branch Newsletter of the Year Award to David A. Rothstein, M.D., Editor, *The Psychiatric Examiner,* Illinois Psychiatric Society. Dr. Rothstein is in private practice in Chicago, Ill.

After the presentation of awards, Dr. Stone introduced Professor Roberto Mangabeira Unger, Harvard Law School, Cambridge, Mass., who gave the William C. Menninger Memorial Convocation Lecture, "Science, Politics, and Moral Vision in Psychiatry." The convocation was then recessed.

MEETINGS OF THE BOARD OF TRUSTEES

The Board of Trustees met in regular session on Sunday, May 4, and on Thursday, May 8. A complete record of Board transactions will be reported by the Secretary (*AJP,* October 1980).

SPOUSES' ACTIVITIES AND ENTERTAINMENT

The Task Force on Arrangements, chaired by Linn A. Campbell, M.D., planned a variety of activities. General tours of San Francisco were given as well as tours of the Monterey Peninsula, Muir Woods and Sausalito, Marin County, Victorian houses of San Francisco, the Filoli House and gardens, the Audubon Canyon Ranch, and the Napa Valley wine country. Other activities included Chinese cooking demonstrations, a visit to the Conservatory and to Asian and French art collections, an architectural antique expedition, a sunset cocktail cruise, and behind-the-scenes observation of local artists at work.

ALLIED MEETINGS

The following professional associations also held meetings in San Francisco during the week of May 3-9: Academy of Orthomolecular Psychiatry, American Academy of Child Psychiatry, American Academy of Psychiatry and the Law, American Academy of Psychoanalysis, American Association for Geriatric Psychiatry, American Association for Social Psychiatry, American Association of Chairmen of Departments of Psychiatry, American Association of General Hospital Psychiatrists, American Association of Psychiatrists from India, American Board of Forensic Psychiatry, American Psychoanalytic Association, American Society for Adolescent Psychiatry, American Society of Physician Analysts, Association for Academic Psychiatry, Association of Korean-American Psychiatrists, Association of Mental Health Clergy, Behavior Therapy and Research Society, Black Psychiatrists of America, International Psychiatric Association for the Advancement of Electrotherapy, National Association of State Mental Health Program Directors, National Association of State Mental Health Research Institutes, National Association of Veterans Administration Chiefs of Psychiatry, National Guild of Catholic Psychiatrists, Navy Psychiatry, Philippine Psychiatrists in America, Psychiatrists for ERA, Research Assessment and Training Unit New York State Psychiatric Institute, Southern Psychiatric Association, and Turkish American Neuropsychiatric Association.

H. KEITH H. BRODIE, M.D.
Secretary, American Psychiatric Association

The American Board of Psychiatry and Neurology

The following successfully completed the Board examination given in Los Angeles, CA, April 14–15, 1980.

DSM-III

The American Psychiatric Association's First Major Revision of the Psychiatric Nomenclature in 12 Years

This long awaited revision of the **Diagnostic and Statistical Manual of Mental Disorders** has taken five years to develop and field test. The result is a 500-page text which is unsurpassed in its completeness, clinical reliability, and description of criteria and codes for psychiatric diagnostic classification. The book incorporates a revision of the diagnostic classifications of DSM-II with an extensive listing of new diagnostic criteria, decision trees for differential diagnosis, a glossary of technical terms, an annotated comparative listing of DSM-II and DSM-III classifications, and an historical review of ICD-9 and ICD-9-CM classifications.

A Compact, Quick-Reference Guide

In making a DSM-III diagnosis, clinicians and researchers may find it convenient to consult the **Quick Reference to the Diagnostic Criteria,** a pocket-sized booklet that contains only the classification, the diagnostic criteria, and a listing of the most important conditions to be considered in a differential diagnosis of each category.

Order Now. Mail coupon to The American Psychiatric Association, Publication Sales, 1700 18th Street, N.W., Washington, D.C. 20009.

Please send me _____ copies of **DSM-III** (hardbound edition), Order #143 @ $25.00.

_____ copies of the **DSM-III** (paperback edition), Order #143-1 @ $20.00.

_____ copies of the **Quick Reference to the Diagnostic Criteria** (paperback), Order #144 @ $10.00

_____ sets (Hardbound **DSM-III** and **Quick Reference to the Diagnostic Criteria**), Order #407 @ $31.00.

Bulk discounts: 10–24 copies, 10% discount per title; 25–99 copies, 15% discount per title; 100 or more copies, 20% discount per title. No bulk discount is available on the Set.

ENCLOSED IS A TOTAL PAYMENT OF $ _____.

(All domestic orders amounting to $35.00 or less must be accompanied by payment. All foreign orders, regardless of dollar amount, must be accompanied by payment. Non-prepaid orders (over $35.00) will be invoiced with shipping/handling charges included.)

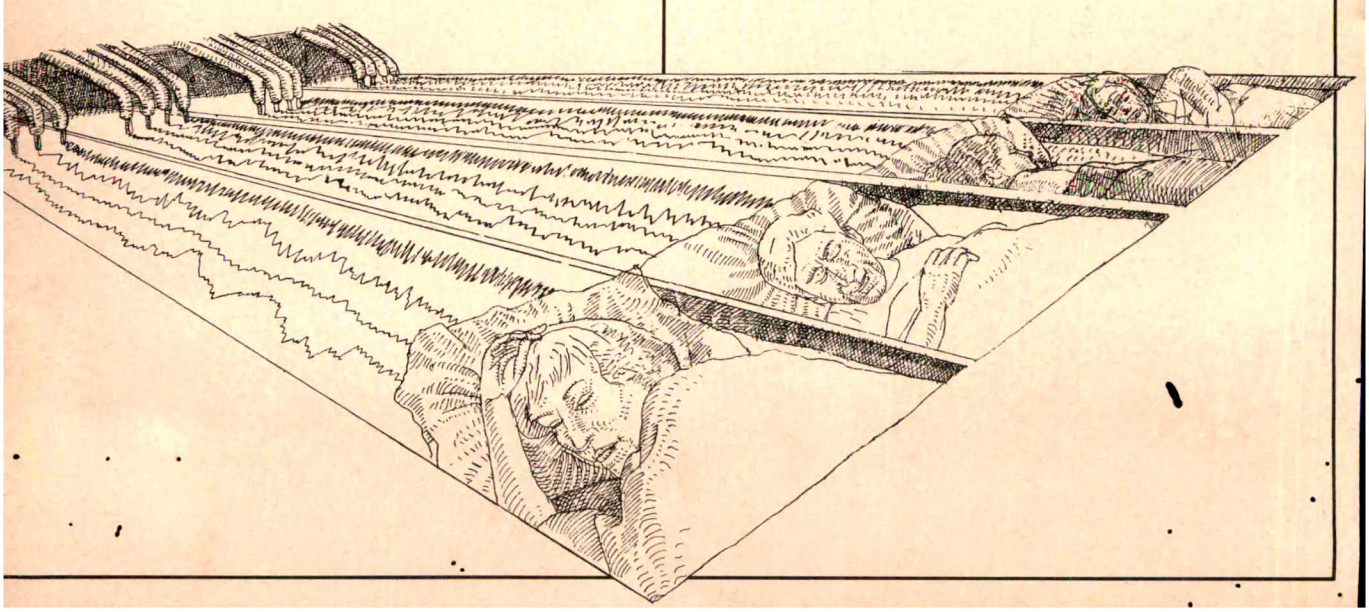
DALMANE
(flurazepam HCl/Roche)

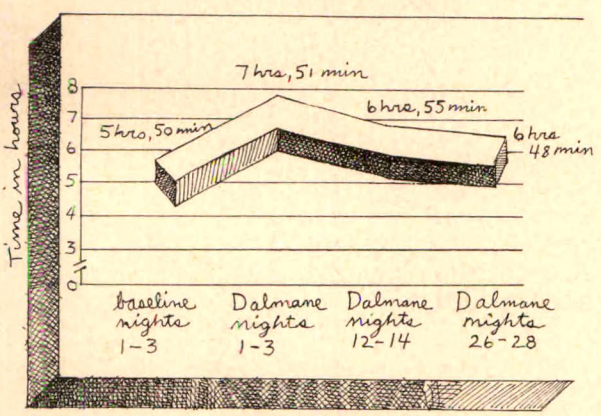


MORE POLYGRAPHIC EVIDENCE

Sleep research laboratory testing of insomnia patients for 995 subject nights demonstrates efficacy of Dalmane (flurazepam HCl/Roche)[1]

In 14 separate studies, subjects given Dalmane were monitored with polygraphic recordings for a total of 995 nights, objectively demonstrating the efficacy of Dalmane.

Efficacy from the first night through 28 nights, without need to increase dosage



Dalmane (flurazepam HCl/Roche) is the only sleep medication objectively proven effective through 28 consecutive nights of administration in two separate studies in the sleep research laboratory.[2-4] The prolonged use of Dalmane is seldom necessary; should it be, appropriate patient evaluations such as periodic blood counts and liver and kidney function tests are recommended.

)FFERS

)F EFFICACY FOR INSOMNIA

Dalmane® (flurazepam HCl/Roche) improved sleep during short, intermediate and longer-term use

Improvement shown represents mean improvement, in hours, of total sleep time. n=5

Adapted from Dement WC, *et al: Behav Med* 5:25-31, Oct 1978

Since most insomnia is transitory in nature, initiate therapy at the lowest effective dose for the shortest time advisable to achieve a predetermined therapeutic goal.

References:
1. Data on file, Medical Department, Hoffmann-La Roche Inc., Nutley NJ
2. Kales A, *et al: Clin Pharmacol Ther 19:* 576-583, May 1976
3. Dement WC, *et al: Behav Med 5:* 25-31, Oct 1978
4. Kales A, *et al: Clin Pharmacol Ther 18:* 356-363, Sep 1975

Clinical documentation of efficacy in 4950 patients with insomnia[1]

Dalmane (flurazepam HCl/Roche) efficacy was evaluated in 18 clinical studies. These included paired-night, double-blind crossover, double-blind comparison and patient preference studies. Results of these studies demonstrated and confirmed the effectiveness of Dalmane.

Periodic evaluation of patient's sleep habits may help prevent subsequent insomnia

Should insomnia recur, the patient may need guidance in setting up a regular sleep program. This may include establishment of a regular bedtime hour, taking a warm bath prior to retiring and avoidance of alcohol, stimulants or heavy meals late in the evening.

DALMANE® (IV)

flurazepam HCl/Roche
15-mg and 30-mg capsules

UNMATCHED PROOF, UNMATCHED EFFICACY

Please see summary of product information on following page.

ROCHE®

Protocol for insomnia management

☐ Treat physical and/or psychological factors that may underlie an inability to sleep.

☐ Thoroughly question and evaluate new patients who specifically request sleep medications.

☐ Consider other medications the patient may be taking (including alcoholic beverages) and be aware of possible drug interactions.

☐ Select a sleep medication with objectively *documented* proof of efficacy and a wide margin of safety.

☐ Initiate treatment at the lowest effective dose for the period of time deemed necessary *to achieve a reasonable therapeutic goal.*

☐ Monitor response to therapy and, based upon patient reassessment, determine need for continuing medication on an individual basis.

☐ Advise patients who ingest alcoholic beverages or other CNS depressants against doing so while on sleep medication. CNS stimulants such as caffeine should also be discontinued.

☐ Caution patients against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving a motor vehicle shortly after ingesting the drug. In addition, as with all CNS depressants, patients may have reduced motor performance while on hypnotic therapy and should be advised accordingly.

☐ Avoid prescribing for suicidal or dependency-prone individuals whose histories indicate an inability to handle any psychoactive substances including alcohol.

Now available from Roche—important guidance for your patients with insomnia.

DA-5T

DALMANE® C-IV
flurazepam HCl/Roche

One 15-mg capsule *h.s.*—recommended initial dosage for elderly or debilitated patients.
One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Objective sleep laboratory data have shown effectiveness for at least 28 consecutive nights of administration. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).

Usage in Pregnancy: **Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane, a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated patients, it is recommended that the dosage be limited to 15 mg to reduce risk of oversedation, dizziness, confusion and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies, or with impaired renal or hepatic function. Periodic blood counts and liver and kidney function tests are advised during repeated therapy.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect.
Adults: 30 mg usual dosage; 15 mg may suffice in some patients.
Elderly or debilitated patients: 15 mg recommended initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

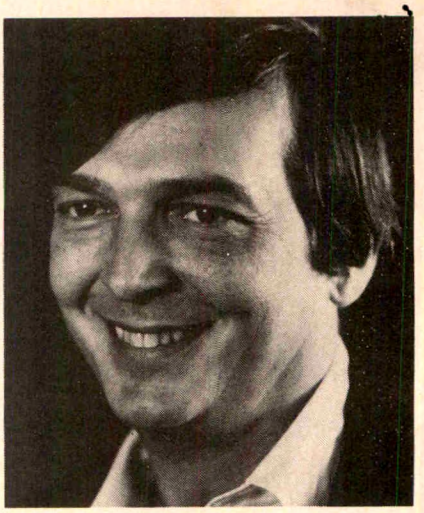
Why Red Cross CPR training is good for your business...

Take it from Andy Machak, automotive electrical plant foreman: "I'm alive today because a fellow employee was trained in CPR.

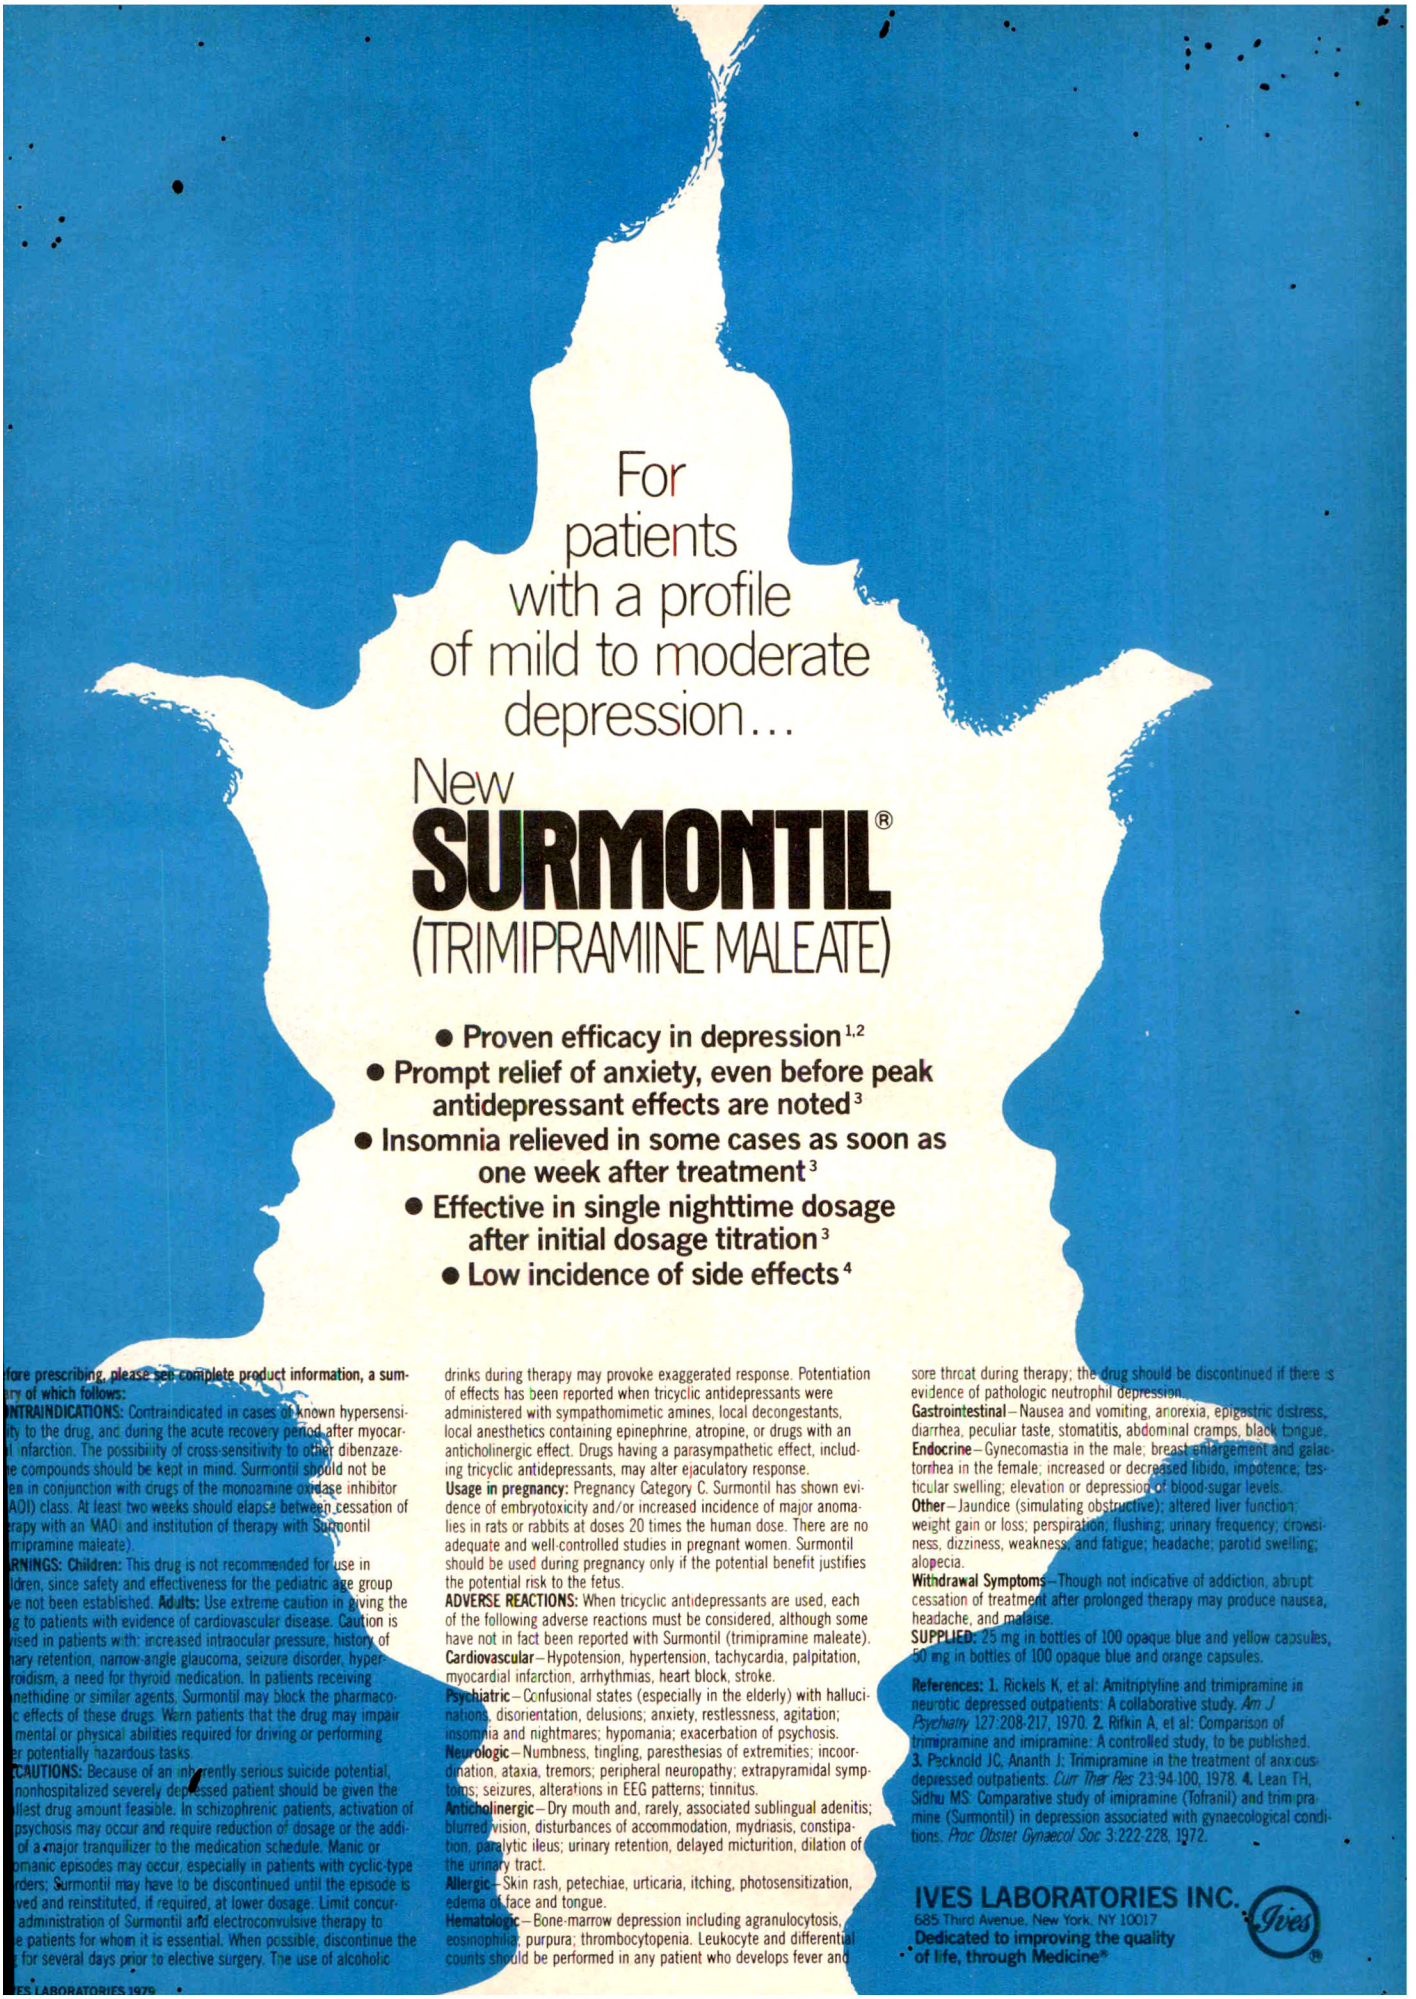


"Cardiopulmonary resuscitation training was one valuable asset that day. I got caught in some heavy machinery at the plant and blacked out.

"They told me later it took six guys to free me. I wasn't breathing. My heart stopped. One of the guys, Don Guarino, said, 'I gotta try anyway.'

"Thanks to his CPR training, he revived me – saved my life.

"Since that happened I realize that no employee is immune from heart attacks or accidents, and a few CPR-trained employees – maybe one for every 50 people – can make the difference between life and death."



Call your Red Cross Chapter and find out about CPR training for your plant or office. CPR training is a valuable asset for any business.

It takes steady, trained hands to perform CPR.

American Red Cross

fore prescribing, please see complete product information, a sum-ary of which follows:

NTRAINDICATIONS: Contraindicated in cases of known hypersensi-ity to the drug, and during the acute recovery period after myocar-l infarction. The possibility of cross-sensitivity to other dibenzaze-ne compounds should be kept in mind. Surmontil should not be en in conjunction with drugs of the monoamine oxidase inhibitor AOI) class. At least two weeks should elapse between cessation of erapy with an MAOI and institution of therapy with Surmontil imipramine maleate).

RNINGS: Children: This drug is not recommended for use in ldren, since safety and effectiveness for the pediatric age group ve not been established. **Adults:** Use extreme caution in giving the g to patients with evidence of cardiovascular disease. Caution is vised in patients with: increased intraocular pressure, history of nary retention, narrow-angle glaucoma, seizure disorder, hyper-roidism, a need for thyroid medication. In patients receiving nethidine or similar agents, Surmontil may block the pharmaco-c effects of these drugs. Warn patients that the drug may impair mental or physical abilities required for driving or performing er potentially hazardous tasks.

CAUTIONS: Because of an inherently serious suicide potential, nonhospitalized severely depressed patient should be given the allest drug amount feasible. In schizophrenic patients, activation of psychosis may occur and require reduction of dosage or the addi-of a major tranquilizer to the medication schedule. Manic or pmanic episodes may occur, especially in patients with cyclic-type rders; Surmontil may have to be discontinued until the episode is ved and reinstituted, if required, at lower dosage. Limit concur-administration of Surmontil and electroconvulsive therapy to e patients for whom it is essential. When possible, discontinue the for several days prior to elective surgery. The use of alcoholic drinks during therapy may provoke exaggerated response. Potentiation of effects has been reported when tricyclic antidepressants were administered with sympathomimetic amines, local decongestants, local anesthetics containing epinephrine, atropine, or drugs with an anticholinergic effect. Drugs having a parasympathetic effect, including tricyclic antidepressants, may alter ejaculatory response.

Usage in pregnancy: Pregnancy Category C. Surmontil has shown evidence of embryotoxicity and/or increased incidence of major anomalies in rats or rabbits at doses 20 times the human dose. There are no adequate and well-controlled studies in pregnant women. Surmontil should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

ADVERSE REACTIONS: When tricyclic antidepressants are used, each of the following adverse reactions must be considered, although some have not in fact been reported with Surmontil (trimipramine maleate).

Cardiovascular—Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric—Confusional states (especially in the elderly) with hallucinations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic—Numbness, tingling, paresthesias of extremities; incoordination, ataxia, tremors; peripheral neuropathy; extrapyramidal symptoms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic—Dry mouth and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis, constipation, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

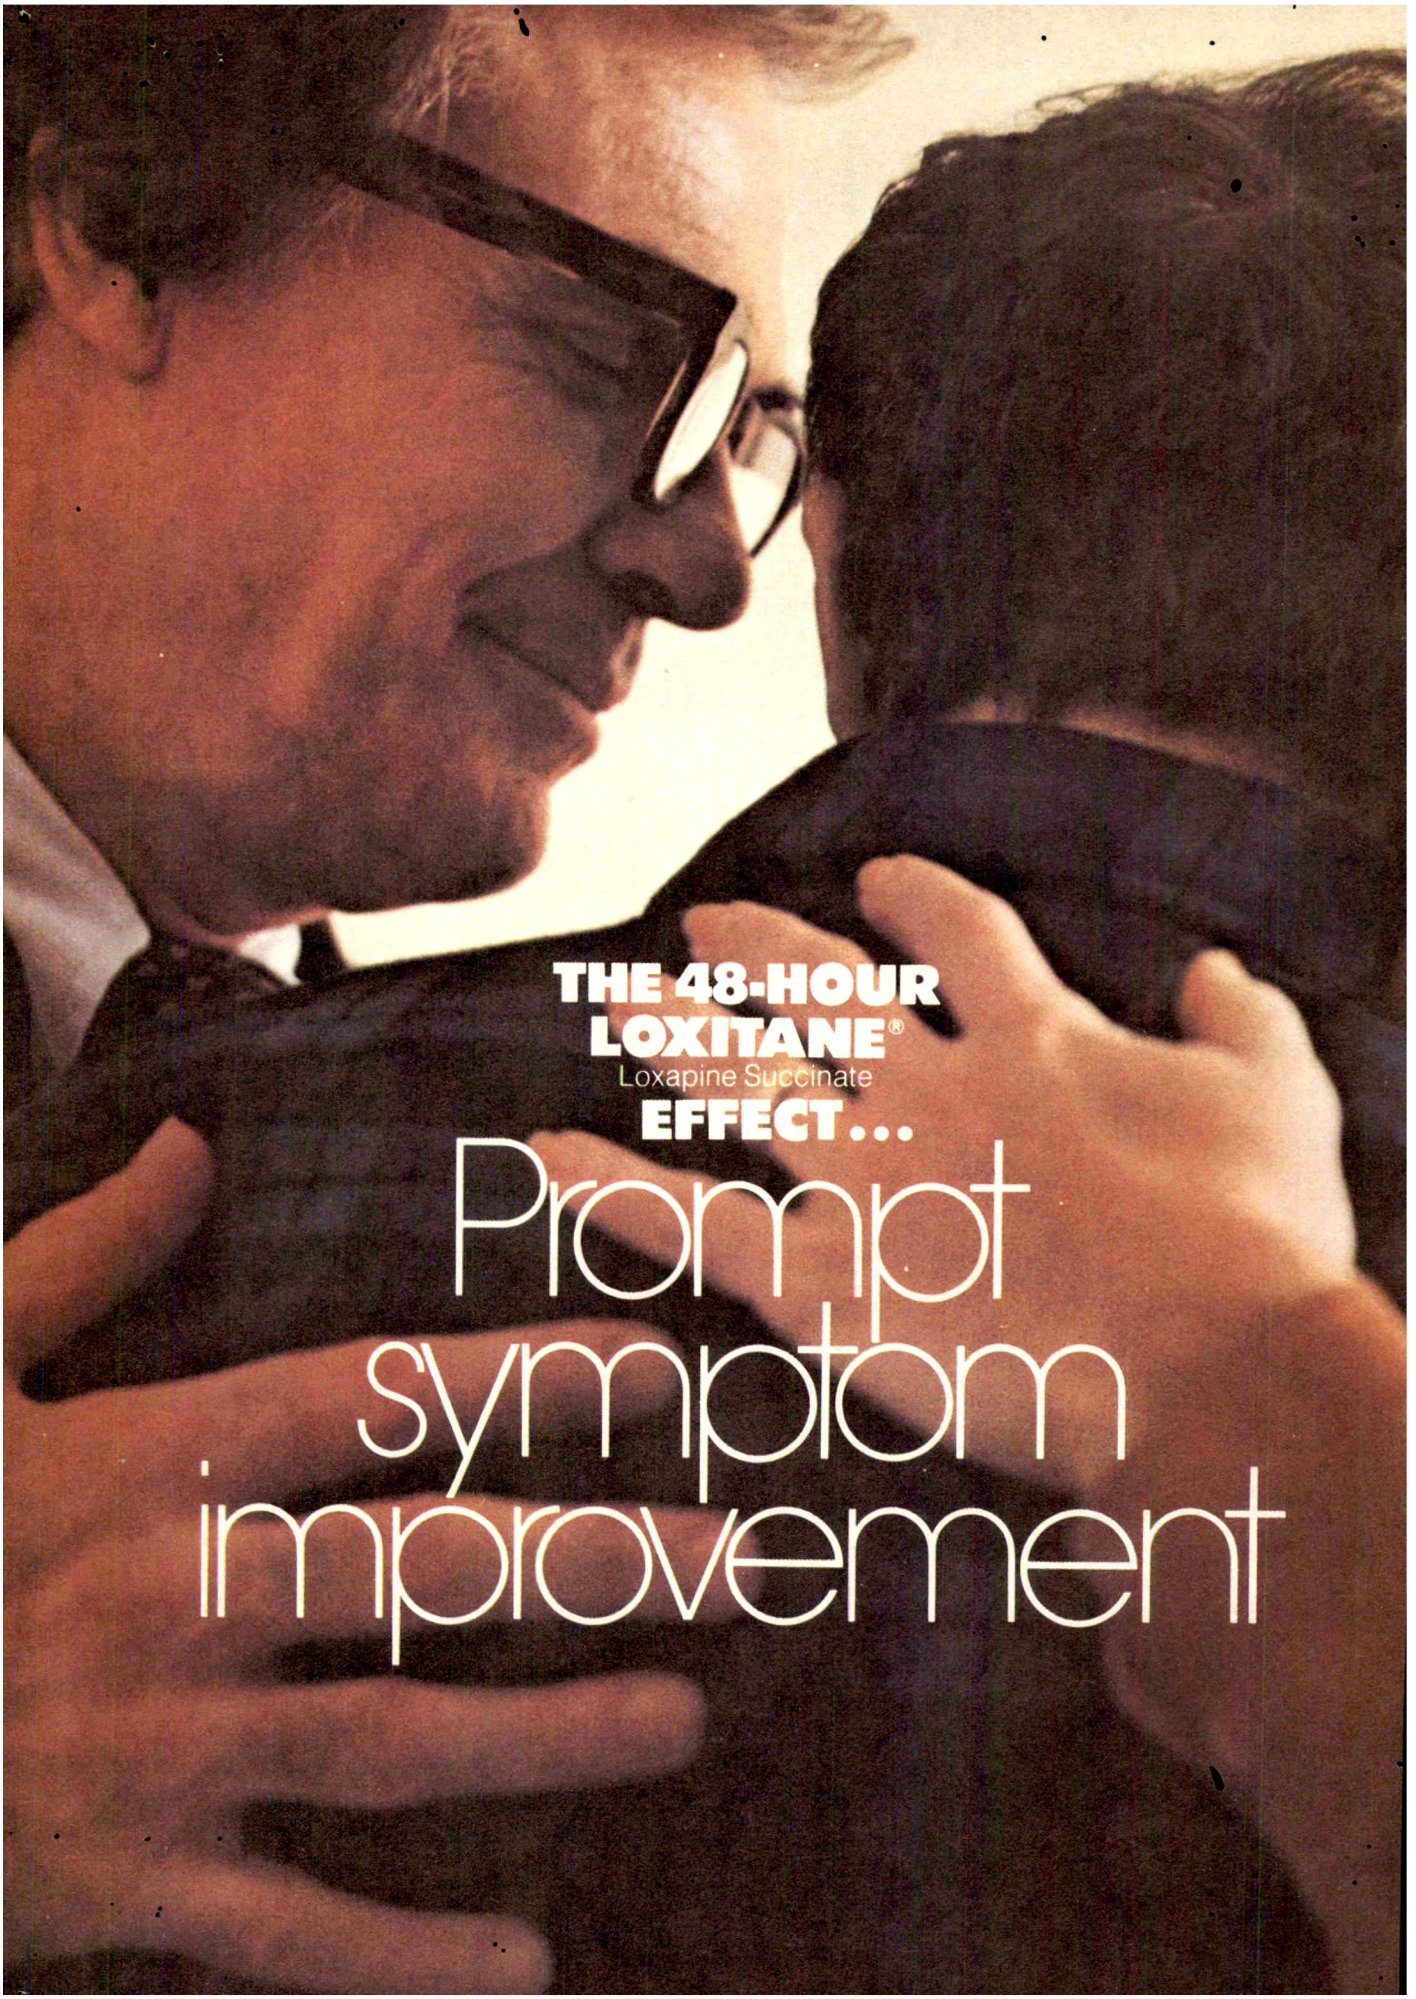
Allergic—Skin rash, petechiae, urticaria, itching, photosensitization, edema of face and tongue.

Hematologic—Bone-marrow depression including agranulocytosis, eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

Gastrointestinal—Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine—Gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood-sugar levels.

Other—Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration, flushing; urinary frequency; drowsiness, dizziness, weakness, and fatigue; headache; parotid swelling; alopecia.



Withdrawal Symptoms—Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

SUPPLIED: 25 mg in bottles of 100 opaque blue and yellow capsules, 50 mg in bottles of 100 opaque blue and orange capsules.

EFFECT...
Prompt
symptom
improvement

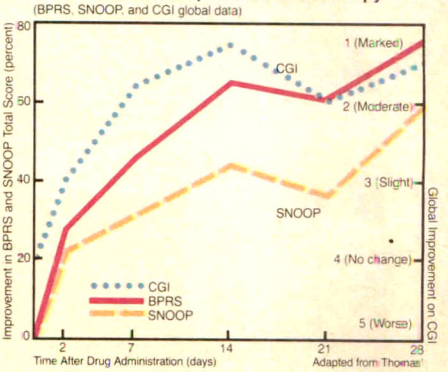
Early response—the first step toward early resocialization

After a relatively short time on LOXITANE® Loxapine Succinate, hospitalized schizophrenic patients usually become easier to reach, easier to manage, more sociable, and cooperative. A series of clinical studies[1-4] shows an impressive decrease in conceptual disorganization, thinking disorder, hallucinatory behavior and anxiety-depression during the first 48 hours.

The results in one group of 17 young adult schizophrenics treated at a university hospital typify general clinical experience. In the first 48 hours, these patients achieved a mean overall symptomatic improvement of more than 20% in BPRS.[1] (See chart)

Continued overall improvement... helps facilitate a return to more normal activities

Near maximal control was reported by week four; many behavior patterns approached normal. In other studies, a mean overall improvement of almost 80% was seen by 28 days.[2,3] Prompt therapeutic response and steady progress can help strengthen the patient's capacity to cope with daily living and relationships.



Minimal risk of certain toxicities... encourages compliance

On LOXITANE, physical health is rarely compromised by certain toxicities.* Renal, hematopoietic, cardiotoxicity, phototoxicity and photosensitivity have not been reported to date.* Therapy in most cases is not interrupted by intolerable side effects. Sexual side effects have not been a significant problem; anticholinergic effects are usually mild, and extrapyramidal reactions are generally easily controlled. Well-tolerated LOXITANE means less frequent need to interrupt therapy—fewer problems with patient compliance.

Note: LOXITANE, as with certain other neuroleptics, lowers the convulsive threshold and should be used with extreme caution in patients with a history of convulsive disorders.

*Although not reported to date, the possibility of phototoxicity, cardiac, renal, or blood toxicity cannot be ruled out at this time. Transient liver enzyme changes not definitely related to LOXITANE have been reported.

Mean improvement in 17 schizophrenic patients on LOXITANE® Loxapine Succinate therapy

For the difference that begins with rapid action...

Loxitane®
LOXAPINE SUCCINATE
Lederle

Recommended Daily Dosage

Dosage	Initially: 20-50 mg During first 24 hours: up to 100 mg Usual therapeutic level: 150 mg/day Maintenance: 60-100 mg/day Maximum: 250 mg/day Dosage may be divided as necessary. Reduced dosage in geriatrics and adolescents should be considered.

Brief Summary
LOXITANE® Loxapine Succinate Capsules
LOXITANE® C Loxapine Hydrochloride Oral Concentrate
LOXITANE® IM Loxapine Hydrochloride

INDICATIONS: Manifestations of schizophrenia.
CONTRAINDICATIONS: Comatose or severely depressed states; hypersensitivity to the drug.
WARNINGS: Safe use during pregnancy or lactation has not been established; weigh potential benefits against possible hazards. Not recommended for use in children under 16. May impair mental and/or physical abilities especially during early therapy; warn ambulatory patients about activities requiring alertness and concomitant use of alcohol or other CNS depressants. Not recommended for management of behavioral complications in mentally retarded patients.
PRECAUTIONS: Use with extreme caution in patients with a history of convulsive disorders; use with caution in patients with cardiovascular disease or in those with glaucoma or a tendency to urinary retention particularly when on concomitant anticholinergic medication. Loxapine has an antiemetic effect in animals which might occur in man masking signs of overdosage of toxic drugs and obscuring intestinal obstruction or brain tumor. Since possible ocular toxicity cannot be excluded, observe carefully for pigmentary retinopathy and lenticular pigmentation. Slightly higher incidence of extrapyramidal effects possible following IM administration.
ADVERSE REACTIONS: *CNS effects,* other than extrapyramidal, infrequent. Mild drowsiness may occur at beginning of therapy or upon dosage increase, usually subsides with continued therapy. Sedation, dizziness, faintness, staggering gait, muscle twitching, weakness and confusional states have been reported. Extrapyramidal reactions often occur early in treatment, manifested by Parkinson-like symptoms (tremor, rigidity, excessive salivation, masked facies, akathisia); controllable by dosage reduction or antiparkinson drugs at usual dosages. Dystonic and dyskinetic reactions, while less frequently occurring, may be more severe, requiring dosage reduction or temporary withdrawal plus appropriate counteractive drugs. *Persistent Tardive Dyskinesia* may appear during prolonged therapy or following discontinuance, the risk greater in the elderly, especially females, on high dosage. Symptoms, persistent and in some patients apparently irreversible, are characterized by rhythmical involuntary movement of the tongue, face, mouth and jaw sometimes accompanied by involuntary movement of extremities. Since there is no known effective treatment, discontinue all antipsychotic drugs if symptoms appear. Reinstitution of treatment, increased dosage or switching to another agent may mask syndrome. The syndrome may not develop if medication is stopped when fine vermicular movements of the tongue first appear. *Cardiovascular Effects:* Tachycardia, hypotension, hypertension, lightheadedness and syncope. ECG changes, not known to be related to loxapine use, have been reported. *Skin:* Dermatitis, edema of face, pruritus, seborrhea. Possible photosensitivity and/or phototoxicity; skin rashes of unknown etiology seen in a few patients in hot summer months. *Anticholinergic:* Dry mouth, nasal congestion, constipation, blurred vision (more likely to occur with concomitant use of antiparkinson agents). *Other:* Nausea, vomiting, weight gain or loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, polydipsia. Rarely, galactorrhea and menstrual irregularity of unknown etiology.

SURVEY OF PSYCHIATRY

APA's first self-study psychiatric review course approved for category I credit

This *new* 16-hour program offers a fresh, comprehensive overview of psychiatric theory, practice, and research. Authored by a distinguished faculty, specialists in their field, SURVEY OF PSYCHIATRY presents *completely new,* up-to-date information for the practicing physician who wants to keep abreast of the current state of the art, and may assist for certifying exams (such as the American Board of Psychiatry and Neurology).

Course Director:
Shervert H. Frazier, MD.
Psychiatrist-in-Chief
McLean Hospital Professor of Psychiatry
Harvard Medical School

SURVEY OF PSYCHIATRY has been designed to meet the needs of the busy physician.

- Versatile programs — ideal for home study, teaching, seminars, group study, and refresher courses
- Maximum educational and review benefits in easy-to-use format
- Convenient, flexible — no time spent away from practice

Course Components:

- Audiocassettes — 14 live lectures on 14 audiocassettes
- Course Syllabus (94 pages) — fully illustrated with tables, charts and slide reproductions, plus a concise bibliography for further study
- Test Section — questions and computerized test sheet with self-addressed mailing envelope for registrants desiring Continuing Medical Education Category I credits

Credit Statement:
As an organization accredited by the Liaison Committee on Continuing Medical Education (LCCME) to provide continuing medical education, the American Psychiatric Association certifies that this continuing medical education offering meets the criteria for up to 16 hours of LCCME Category I CME credit, provided it is used and completed as designed.

Order Form

THE CHRONIC MENTAL PATIENT

Report of a Conference held in January 1978
Edited by
John A. Talbott, M.D.

with contributions by James T. Barter, M.D., Paul R. Friedman, J.D., Raymond Glasscote, M.A., Trevor D. Glenn, M.D., Norman V. Lourie, M.S.W., W. Walter Menninger, M.D., Arthur T. Meyerson, M.D., Kenneth Minkoff, M.D., Samuel Muszynski, M.S.W., Lucy D. Ozarin, M.D., Gordon L. Paul, Ph.D., Ronald Peterson, Steven S. Sharfstein, M.D., Judith Clark Turner, Jane Bloom Yohalem, J.D.

This 277-page Report of the Conference, sponsored by APA and President Carter's Commission on Mental Health, identifies the chronic mental patient population, spells out where they are and what their needs and rights are. It specifies what programs work and what programs do not work in meeting the needs of these patients. It elaborates on the obstacles to implementing effective programs and the economic issues involved. It delineates the pros and cons of case management and specifies responsibility for coordinating, implementing, and monitoring services to chronic mental patients.

Finally, it proposes a *Call to Action* which opens with this statement: "There is no more urgent concern than the needs of the chronic mentally ill who suffer from severe, persistent, or recurrent mental illnesses with residual social and vocational disabilities. As a result of the deinstitutionalization programs of the past decade and the continuing growth of high risk populations that generate chronically ill, the problems associated with the care of these patients constitute a national crisis."

Since the Conference, the APA Assembly and the Board of Trustees have both approved the "Call to Action" which calls upon the APA to take the lead in undertaking programs to elevate the prestige and value of work with chronic mentally ill patients.

It follows that all APA members should be thoroughly versed in the current problems of this chronic patient population. This is best accomplished by reading this Conference Report now available from APA Publications Services at $11.00 a copy.

Introducing...

Navane®
(thiothixene HCl)
Intramuscular
For Injection
5 mg/ml

new potency for rapid control of acute psychiatric emergencies

Now, Navane Intramuscular 5 mg per ml provides a more concentrate dosage form for rapid control of severely disturbed behavior associat ed with acute psychosis. Navane Intramuscular, in carefully monitor ed doses, "...can produce significan improvement within hours and increase the accessibility of these [acutely disturbed] patients to mor gradual methods of pharmacologica treatment as well as to socio-enviro mental intervention and psycho-therapy."[1]

Rapid tranquilization usually ca be achieved without excessive seda-tion.[1] Clinically significant hypoten-sion, often seen with other injectab antipsychotic agents, is rare with Navane Intramuscular therapy.[1-3] If extrapyramidal symptoms occur, they are usually readily controlled by dosage adjustment or antiparkin son agents.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

For a brief summary of Navane prescribing information, including adverse reactions and contraindications, please see the following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml, 5 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml, 5 mg/ml

Contraindications. Navane (thiothixene) is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*– Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration of Navane to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children– The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration– As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution; Navane For Injection– Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane (thiothixene) Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate– In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Stimulants that may cause convulsions (e.g. picrotoxin or pentylenetetrazol) should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100, 1,000, and unit-dose pack of 100 (10 x 10's). Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100, 500, and unit-dose pack of 100 (10 x 10's).

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10 vials. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

Navane (thiothixene hydrochloride) Intramuscular For Injection is available in amber glass vials in packages of 10 vials. When reconstituted with 2.2 ml of Sterile Water for Injection, each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene, and 59.6 mg of mannitol. The reconstituted solution of Navane Intramuscular For Injection may be stored for 48 hours at room temperature before discarding.

MEDICAL DIRECTOR

Psychiatry

Large Psychiatric Service of a major West Coast Medical Center is currently recruiting for a Medical Director/Psychiatry. The successful candidate will have

1. Board Certification in Psychiatry;
2. Minimum 3-5 year's post-residency psychiatric experience in hospital psychiatry;
3. Knowledge of laws and regulations affecting mental health; and
4. Prefer experience in program planning and direction of a Psychiatric Center.

Negotiable salary and excellent benefit package. For confidential consideration send resume or curriculum vitae to:

Box J-542

Equal Opportunity Employer M/F

ALABAMA MENTAL HEALTH INSTITUTE

Alabama Mental Health Department is currently recruiting General Primary Care Physicians and Psychiatrists. Positions are available in 11 locations, including Montgomery, Mobile and Tuscaloosa. We offer competitive salaries, 40 hour work week, a liberal benefits package, free health package and paid interviewing and relocation expenses. Alabama, with year round good weather, offers excellent recreation advantages, including theatre and the arts. Alabama is the place where good living and gracious manners are still the lifestyle. Our consultants can provide more information on interviewing qualified candidates. To find out more about these exciting opportunities, call our toll-free number listed below:

Alabama Mental Health Institute
JACKSON & COKER
448-PA N. Shallowford Road
Suite 1040
Atlanta, Georgia 30338

PSYCHIATRIST

CERTIFIED

Professor (for position of Associate/or higher depending on qualifications.)

Must be native Arabic-speaker, with work experience in Arab countries. Preferably with strong background in research and/or clinical psychiatry.

Duties will include teaching research courses in newly established department and work in Public Health Clinic.

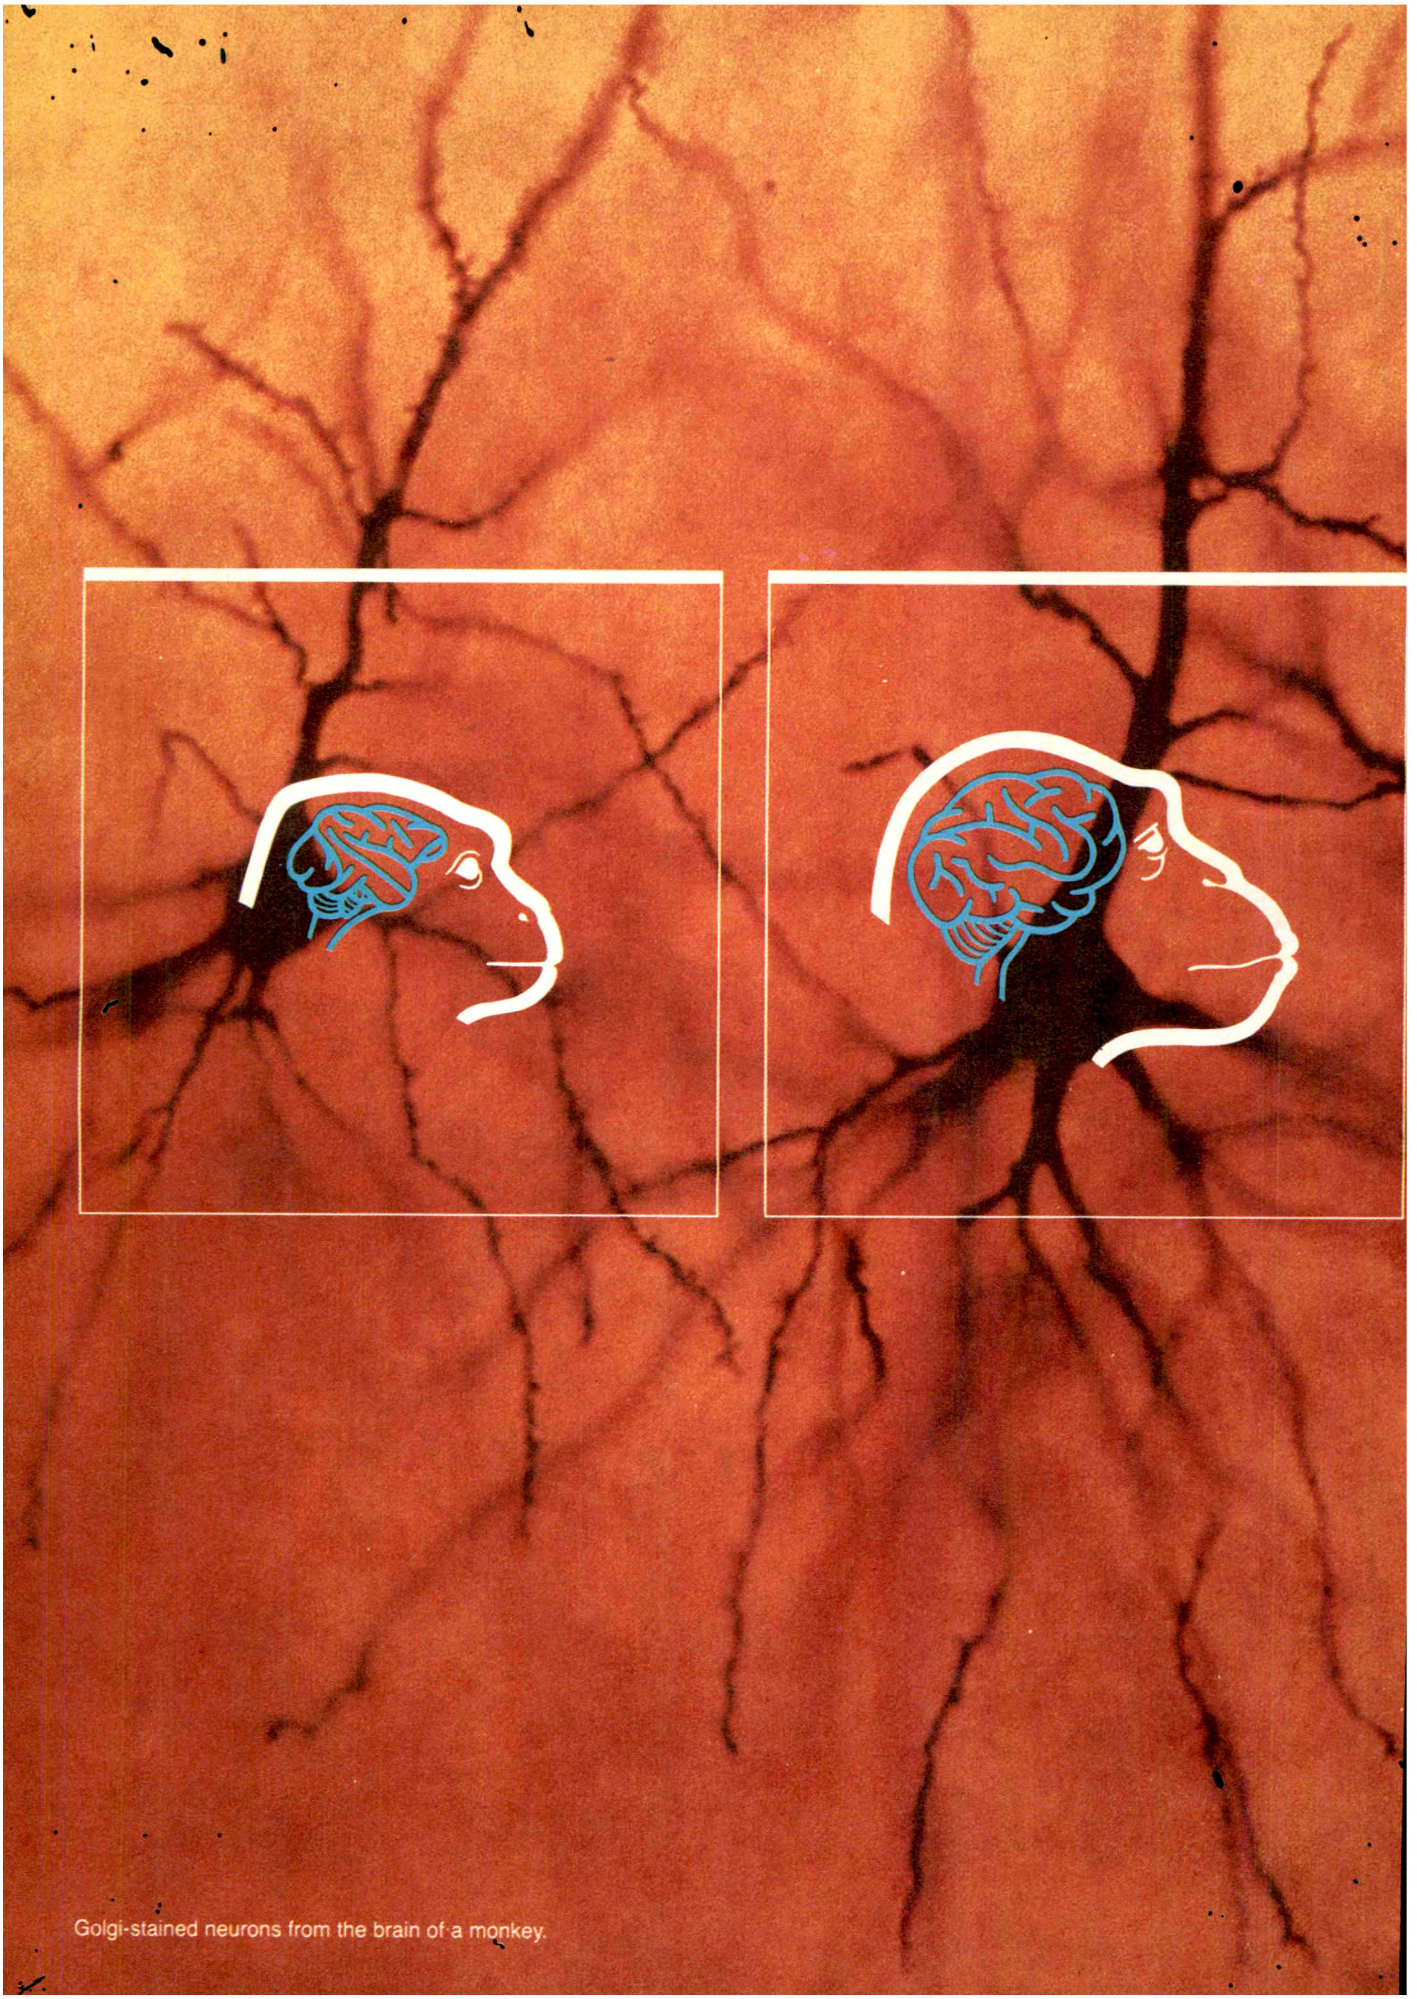
Benefits: separate housing allowance, furniture allowance, insurance coverage for self and family (up to four children under the age of eighteen), tickets to return home (place of recruitment) for self and family for annual vacation, two months bonus salary for each year of service, annual raise.

Salary, negotiable, depending on qualifications.

There are several positions available immediately. Send resume and certified copies of school and professional documents to: University of Garyounis in Benghazi, People's Bureau of The Socialist People's Libyan Arab Jamahiriya, Cultural Section, Post Office Box 19125, Washington, D.C. 20036.

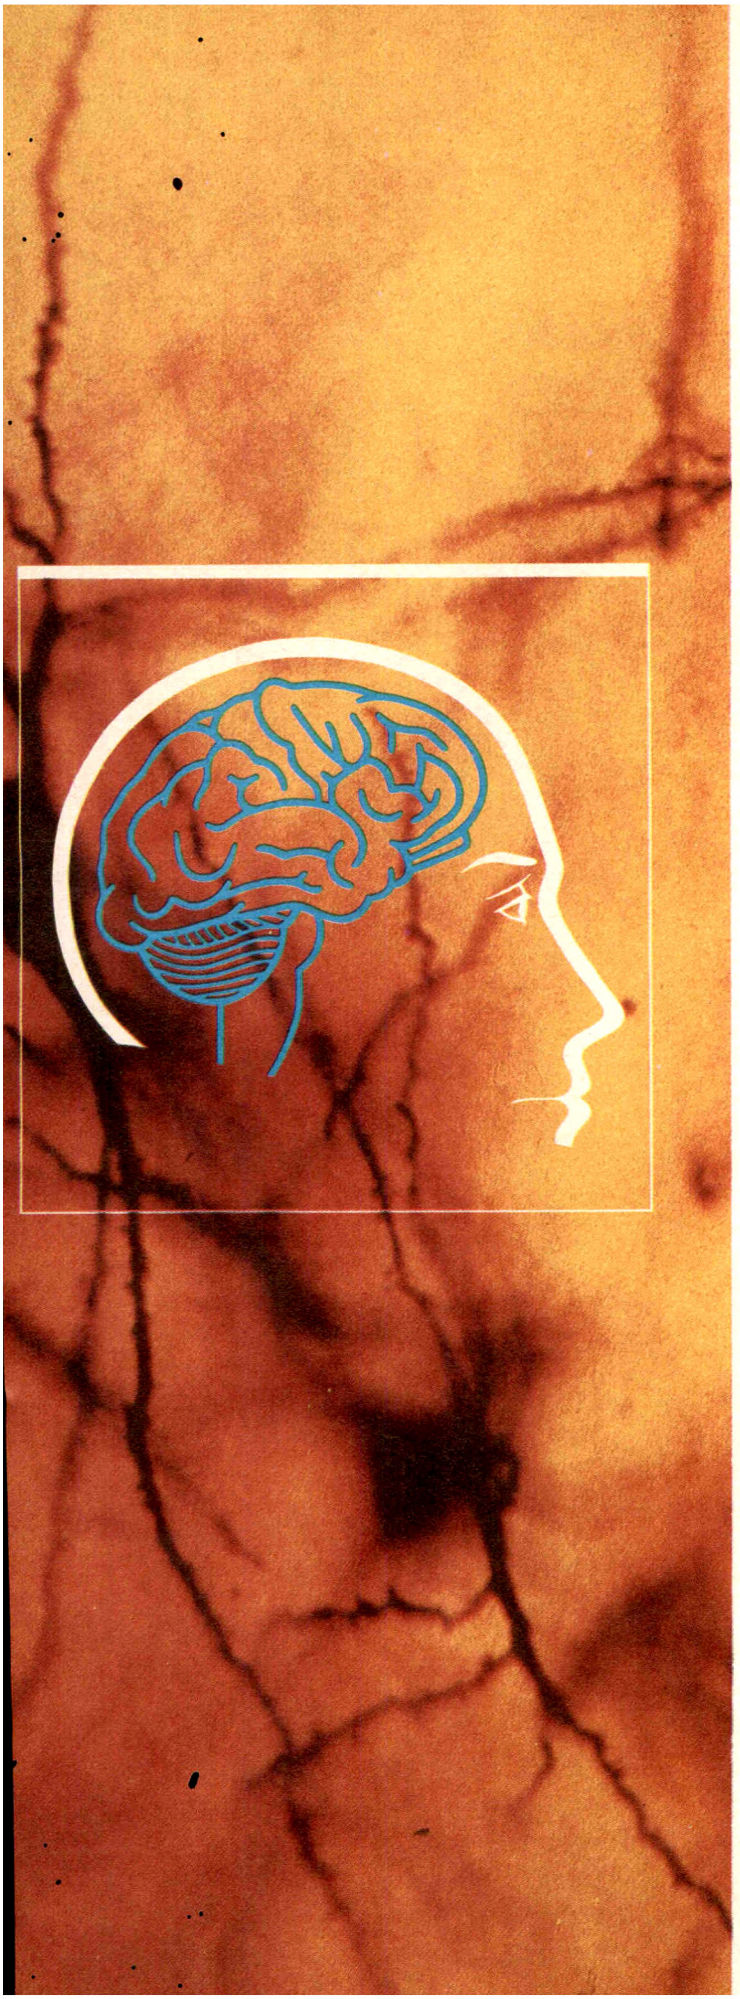
JCAH
M.D./PSYCHIATRIST
SURVEYOR

The Joint Commission on Accreditation of Hospitals offers a unique opportunity for M.D./Psychiatrists who have broad clinical/administrative experience in the mental health field and knowledge of functions and operations of psychiatric hospitals, facilities and programs concerned with adults, children and adolescents, alcoholism, drug abuse and community mental health.



As a Surveyor for the Accreditation Program for Psychiatric Facilities (AP/PF) you will be responsible for a broad spectrum of surveying activities. Evaluating facilities/programs seeking accreditation, conducting medical records workshops, providing consultation on improvements of health care services and facilities are examples of the comprehensive scope of the survey process.

Requirements include Certification in psychiatry by the American Board of Psychiatry and Neurology and current licensure in any U.S. state; clear oral and written communication skills are essential, coupled with the ability to observe, educate and relate well with people.



We offer a challenging position with an exciting opportunity involving extensive travel with all expenses paid. You will earn an excellent salary and enjoy an outstanding benefits program.

Golgi-stained neurons from the brain of a monkey.

Pharmacology Recapitulates Phylogeny

Recently discovered binding sites in the brains of primates and other vertebrates displaying high affinity for benzodiazepines have stimulated the search for an endogenous substance which may interact at these same binding sites and may also have anxiolytic properties.

While the search continues for a naturally produced anxiolytic, you can rely on Librium for predictable patient response in the treatment of anxiety.

Librium® IV

chlordiazepoxide HCl/Roche

5mg, 10mg, 25mg capsules

The origin of the species

ROCHE

Please see next page for summary of product information.

Librium® 5mg, 10mg, 25mg capsules
chlordiazepoxide HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states. Efficacy beyond four months not established by systematic clinical studies. Periodic reassessment of therapy recommended.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Warn patients that mental and/or physical abilities required for tasks such as driving or operating machinery may be impaired, as may be mental alertness in children, and that concomitant use with alcohol or CNS depressants may have an additive effect. Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral–Adults:* Mild and moderate anxiety and tension, 5 or 10 mg *t.i.d.* or *q.i.d.*; severe states, 20 or 25 mg *t.i.d.* or *q.i.d. Geriatric patients:* 5 mg *b.i.d.* to *q.i.d.* (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) *Capsules,* 5 mg, 10 mg and 25 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10. Libritabs® (chlordiazepoxide) *Tablets,* 5 mg, 10 mg and 25 mg—bottles of 100 and 500. With respect to clinical activity, capsules and tablets are indistinguishable.

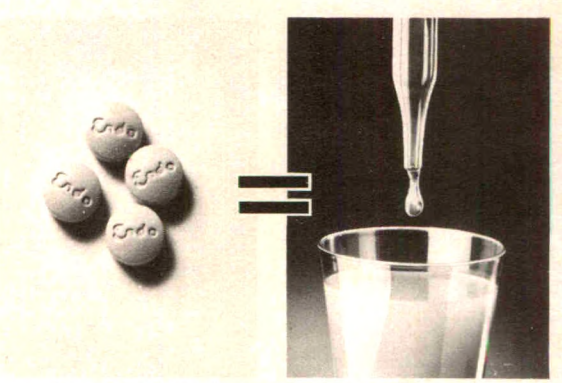
New
MOBAN®
molindone HCl
Concentrate
20 mg/ml
Easily administered
in fruit juice...has
a subtle cherry flavor
when taken alone



An effective antipsychotic agent with a favorable benefit/risk profile

NO incidence	excessive weight gain hepatotoxic changes ophthalmological changes persistent tardive dyskinesia skin pigmentation thyroid function changes tolerance development
LOW incidence	adverse drug interactions hematological changes hypotension nonpersistent symptoms of tardive dyskinesia sedation
MODERATE incidence	extrapyramidal reactions

This table compiled from clinical and field reports, according to the best available information.

For the schizophrenic patient

New MOBAN®
molindone HCl
Concentrate
20 mg/ml

four 25 mg tablets = 5 milliliters (100 mg)

Concentrated for maximum convenience of higher dosages...easy titration... enhanced compliance

Initial dosage with MOBAN®

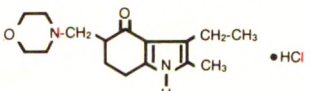
- usual starting dose is 50-75 mg/day
- may be increased to 100 mg/day in three to four days
- may be adjusted up or down according to response
- some patients with severe symptomatology may require an increase to 225 mg/day
- elderly and debilitated patients should be started on lower dosage

Please see next page for prescribing information.

Endo Laboratories DUPONT

A53

An effective antipsychotic agent



MOBAN®
molindone HCl

New dosage form... Concentrate 20 mg/ml

continuing...Tablets 5 mg, 10 mg, 25 mg

DESCRIPTION MOBAN (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditioned response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN being excreted in urine and feces.

INDICATIONS MOBAN (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

MOBAN has not been shown effective in the management of behavioral complications in patients with mental retardation.

PRECAUTIONS Some patients receiving MOBAN (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN. Caution should be exercised where increased activity may be harmful.

MOBAN does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, in humans convulsive seizures have been reported in a few instances.

EDO 854M580

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN (molindone hydrochloride) has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS—CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological—Extrapyramidal Reactions Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia Motor restlessness may occur early.

Parkinson Syndrome Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Galactorrhea and gynecomastia have been reported infrequently. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN.

Cardiovascular Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN.

Skin Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN usage alone.

MOBAN (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia Although rarely reported with MOBAN (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN (molindone hydrochloride) should be individualized.

Initial Dosage Schedule The usual starting dosage is 50-75 mg/day.
- —Increase to 100 mg/day in 3 or 4 days.
- —Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- —An increase to 225 mg/day may be required in patients with severe symptomatology.

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule
1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN (molindone hydrochloride) from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents, (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles with potencies and colors as follows:

100's and 1000's:
5 mg orange
10 mg lavender
25 mg light green

As a concentrate containing 20 mg molindone hydrochloride per ml in 4 oz. (120ml) bottles.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

DUPONT

CLORAZEPATE DIPOTASSIUM

Tranxene® C IV

Ideal for short-term antianxiety therapy

Acts promptly...tapers gently at discontinuation

Tranxene goes to work in minutes

Nordiazepam uptake is rapid, with pharmacologic effects reported within 30 minutes.[1] Peak serum levels are attained within 1-2 hours after dosing.

Allows post-therapy adjustment time

When administration stops, nordiazepam serum levels taper at a gentle rate. This built-in taper gives your patients more time to adjust to cessation of therapy.[2]

1. Sedation reported in patients 30 minutes after dosing. Tranxene Drug Monograph 97-0185, p. 9, 1979.
2. The elimination kinetics of an agent can be closely defined, but these cannot at present be directly related to therapeutic or adverse effects.

Abbott Laboratories, North Chicago, IL 60064

Brief Summary

INDICATIONS — Symptomatic relief of anxiety and tension associated with anxiety disorders, other psychoneurotic disorders, transient situational disturbances, and functional or organic disorders. Symptomatic relief of acute alcohol withdrawal.

Effectiveness in long-term use (over 4 months) not assessed by systematic clinical studies. Physician should periodically reassess usefulness for each patient.

CONTRAINDICATIONS — Known hypersensitivity to the drug. Acute narrow angle glaucoma.

WARNINGS — Not for use in depressive neuroses or psychotic reactions. Caution patients against hazardous occupations requiring mental alertness, such as operating dangerous machinery including motor vehicles. Advise against simultaneous use of other CNS depressants, and caution patients that effects of alcohol may be increased. Not recommended for patients under 18. Nervousness, insomnia, irritability, diarrhea, muscle aches, and memory impairment have followed abrupt withdrawal from long-term high dosage. Withdrawal symptoms were reported after abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months. Use caution in patients having psychological potential for drug dependence (dependence has been observed in dogs and rabbits).

Pregnancy and Lactation: Minor tranquilizers should almost always be avoided first trimester. Consider possibility of pregnancy before initiating therapy. Patient should consult physician about discontinuation if she becomes pregnant or plans pregnancy. Do not give to nursing mothers.

PRECAUTIONS — Observe usual precautions in depression accompanying anxiety, or in patients with suicidal tendency, or those with impaired renal or hepatic function. Do periodic blood counts and liver function tests during prolonged therapy. Use small doses and gradual increments in the elderly or debilitated.

ADVERSE REACTIONS —Drowsiness, dizziness, various g.i. complaints, nervousness, blurred vision, dry mouth, headache, mental confusion, insomnia, transient skin rashes, fatigue, ataxia, genitourinary complaints, irritability, diplopia, depression, slurred speech, abnormal liver and kidney function, decreased hematocrit, decreased systolic blood pressure.

DOSAGE — ANXIETY Usual daily dose 30 mg or less (start the elderly or debilitated at 7.5-15 mg). Adjust gradually within 15-60 mg daily range. Capsules: divided doses; or once daily h.s. (start patient at 15 mg). Single Dose Tablets, 22.5 mg (for patients stabilized on 7.5 mg t.i.d.) or 11.25 mg: once daily at any hour. ALCOHOL WITHDRAWAL In divided doses: 1st day 30 mg initially, then 30-60 mg; 2nd day 45-90 mg; 3rd day 22.5-45 mg; 4th day 15-30 mg. Then taper to 15-7.5 mg daily, and discontinue as soon as stable.

INTERACTIONS —Potentiation may occur with ethyl alcohol, hypnotics, barbiturates, narcotics, phenothiazines, MAO inhibitors, other antidepressants.

OVERDOSAGE — Take general measures as for any CNS depressant.

SUPPLIED — Tranxene (clorazepate dipotassium) 3.75, 7.5, and 15 mg capsules. Tranxene-SD Half Strength 11.25 and Tranxene-SD 22.5 mg single dose tablets. 0043330

Acts promptly...tapers gently at discontinuation

CLORAZEPATE DIPOTASSIUM

Tranxene® C IV

4306CB

Unexcelled choice for short-term management of anxiety

3.75, 7.5, and 15 mg capsules; 11.25 and 22.5 mg single dose tablets.

See overleaf for brief summary.

BACK AMONG
FRIENDS

THORAZINE

brand of

CHLORPROMAZINE

Tablets:
50 and 100 mg
of the HCl

Back among friends—an important source of much-needed support. She went into the hospital with a psychiatric emergency but left more like herself—delusions, hallucinations, and other psychotic target symptoms under control with 'Thorazine'. And 'Thorazine' maintenance can help keep her out of the hospital in the future.

From initial psychiatric emergency through maintenance treatment, 'Thorazine' offers effective antipsychotic therapy with 18 convenient dosage forms and strengths. This means you can precisely tailor dosage to individual patient needs—increasing or decreasing as the situation demands.

'Thorazine'. The most widely tested and highly flexible antipsychotic available today.

Helps return psychotic patients to reality

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications: For the management of manifestations of psychotic disorders. To control the manifestations of the manic type of manic-depressive illness. For the treatment of severe behavioral problems in children marked by combativeness, and/or explosive hyperexcitable behavior (out of proportion to immediate provocations), and in the short-term treatment of hyperactive children who show excessive motor activity with accompanying conduct disorders consisting of some or all of the following symptoms: impulsivity, difficulty sustaining attention, aggressivity, mood lability and poor frustration tolerance.

> Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the other indication as follows:
>
> Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.
>
> Final classification of the less-than-effective indication requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings: The possibility of extrapyramidal reactions from chlorpromazine may confuse the diagnosis of Reye's syndrome or other encephalopathy. Therefore, avoid use in children or adolescents with suspected Reye's syndrome.

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine. Chlorpromazine is excreted in the breast milk of nursing mothers.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Patients with a history of hepatic encephalopathy due to cirrhosis have increased sensitivity to the C.N.S. effects of chlorpromazine. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or obscure diagnosis of conditions such as intestinal obstruction, brain tumor and Reye's syndrome (see Warnings). Discontinue high-dose, long-term therapy gradually. Patients with history of long-term therapy with 'Thorazine' and/or other neuroleptics should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

'Thorazine' tablets contain FD&C Yellow #5 (tartrazine) which may cause allergic-type reactions (including bronchial asthma) in certain susceptible individuals. Although the overall incidence of FD&C Yellow #5 (tartrazine) sensitivity in the general population is low, it is frequently seen in patients who also have aspirin sensitivity. 'Thorazine' tablets are in the process of being reformulated to remove the FD&C Yellow #5. For specific information, contact Smith Kline &French Laboratories (outside Pa., call toll-free: 1-800-523-4835, ext. 4262; in Pa., call collect: 215-854-4262).

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis, contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg. Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

APA PLACEMENT SERVICE

For Employers and Applicants

Those wishing to announce either position openings or availability for employment may register in advance by requesting a listing form by calling Ms. Patricia Anthony (202) 797-4867, or writing to her attention at APA Central Office, 1700 18th Street, N.W., Washington, D.C. 20009. Listing forms should be returned no later than August 29th. On-site listings will also be accepted. However, forms received at the APA prior to the August 29th deadline will have exposure from the very beginning of the institute. There will be a placement booth and an interviewing area located on the plaza level of the Sheraton Boston Hotel. Listings will be accepted for any mental health related position vacancy/availability.

APPLICANTS—$4 for listing availability
EMPLOYERS—$7 for listing job description

Complete sets of all applicants will be available at the close of the Institute at $10.00 per set; complete sets of positions will be available at $15.00 per set. These sets will be mailed two weeks following the Institute.

THE AMERICAN JOURNAL OF PSYCHIATRY

CONTENTS Vol. 137, No. 9 September 1980

1023 Overview: Model Programs for Chronic Mental Patients
Leona L. Bachrach

1032 The Use of ECT in the Treatment of Schizophrenia
Carl Salzman

1042 Effects of Lithium Carbonate on Memory and Other Cognitive Functions
Larry R. Squire, Lewis L. Judd, David S. Janowsky, and Leighton Y. Huey

1047 Couples' Reactions to Male Infertility and Donor Insemination
David M. Berger

1050 The *DSM-III* Personality Disorders Section: A Commentary
Allen Frances

1055 Self-Induced Water Intoxication in Schizophrenic Patients
William O. Smith and Mervin L. Clark

1061 The Prediction of Dangerous Behavior in Emergency Civil Commitment
Ethan S. Rofman, Clifford Askinazi, and Emily Fant

1065 The Mental and Nervous Disorder Utilization and Cost Survey: An Analysis of Insurance for Mental Disorders
O. B. Towery, Steven S. Sharfstein, and Irving D. Goldberg

OPINION AND COMMENT

1071 "Medical Responsibility" in Institutional Settings
Ben Bursten

1075 Comment
Frederick J. Stoddard

EDITORIAL

1079 Are Books and Readers Facing Extinction?
Nancy C. Andreasen

BRIEF COMMUNICATIONS

1081 Use of a Self-Report Symptom Scale to Detect Depression in a Community Sample
Jerome K. Myers and Myrna M. Weissman

1084 A Comparison of Unipolar and Bipolar Depressive Illness
Richard Abrams and Michael Alan Taylor

1088 Predicting Outcome of Antipsychotic Drug Treatment from Early Response
Philip R.A. May, Theodore Van Putten, and Coralee Yale

1090 MHPG as a Predictor of Antidepressant Response to Imipramine and Maprotiline
Alan H. Rosenbaum, Alan F. Schatzberg, Toshihiko Maruta, Paul J. Orsulak, Jonathan O. Cole, Edwin L. Grab, and Joseph J. Schildkraut

1093 Drug-Related Admissions to an Inpatient Psychiatric Unit
Ronald B. Stewart, Philip K. Springer, and John E. Adams

1095 Depression as Expressed in Pre-Columbian Mexican Art
Juan-Ramon de la Fuente and Donato Alarcón-Segovia

1098 Treatment of Persons Found Incompetent to Stand Trial
Linda Pendleton

1101 Interpersonal Factors in the Psychiatry Clerkship: New Findings
Carole S. Orleans, Jeffrey L. Houpt, and David B. Larson

1104 Psychiatric Residents' Attitudes Toward Teaching
Kenneth E. Callen and John M. Roberts

CLINICAL AND RESEARCH REPORTS

1107 Intoxication Associated with Lithium and ECT, *M.R. Mandel et al*
1109 Treatment of the Child Pornography Patient, *U.C. Schoettle*
1111 ECT and Cardiac Patients with Pacemakers, *G.S. Alexopoulos et al*
1112 Cimetidine Toxicity Manifested as Paranoia and Hallucinations, *L.E. Adler et al*
1113 A Case Report of Lorazepam Withdrawal, *R.B. Stewart et al*
1115 Changing Perceptions of the Mental Health Needs of Inmates in Local Jails, *H.J. Steadman et al*
1117 Prolactin Changes in Major Depressive Disorders, *G.M. Asnis et al*
1118 Acetylcholinesterase and Pseudocholinesterase Activities in Anxiety, *R.J. Mathew et al*
1121 Clonidine for Opiate Detoxification: Outpatient Clinical Trials, *A.M. Washton et al*
1123 Differences Between Psychologists and Psychiatrists in the Use of *DSM-III*, *L.C. Morey*

1125 LETTERS TO THE EDITOR

1132 Correction: Ronald B. Stewart, Barry Karas, and Philip K. Springer: "Haloperidol Excretion in Human Milk" (137:849, 1980).

1133 BOOK FORUM

A65 Index to Advertisers

Information for Contributors

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material, have not been published previously, are not being considered for publication elsewhere, and have been approved by each author.

Copyright

The *Journal* requires express transfer of copyright to the American Psychiatric Association so that the author(s) and the Association are protected from misuse of copyrighted material. Authors of accepted papers will be asked to sign the following statement:

In consideration of the *American Journal of Psychiatry*'s taking action in reviewing and editing my submission [include title here] the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the American Psychiatric Association in the event that such work is published by the American Psychiatric Association.

Work done as part of an individual's duties as a federal employee is in the public domain. In such cases the following wording should be used:

The work described in [include title here] was done as part of my (our) employment with the federal government and is therefore in the public domain.

In addition, authors must obtain letters of permission from publishers for use of extensive quotations (more than 500 words) and of tables and figures that originally appeared elsewhere.

Patient Anonymity

Ethical as well as legal considerations require careful attention to the protection of a patient's anonymity in case reports and elsewhere. Identifying information such as names, initials, hospital numbers, and dates must be avoided. In addition, authors should disguise identifying information about a patient's characteristics and personal history.

Informed Consent

Manuscripts that report the results of experimental investigation with human subjects must include a statement that informed consent was obtained after the procedure(s) had been fully explained.

Review Process

Papers are reviewed by at least two experts to determine the originality, validity, and significance of content and conclusions. Authors will usually be advised within 3–4 months of the decision on their paper, although delays are sometimes unavoidable. Reviewers' comments will be returned with rejected manuscripts if they are judged to be useful to the authors. All reviewers remain anonymous.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in triplicate to John C. Nemiah, M.D., Editor, *American Journal of Psychiatry*, 1700 Eighteenth St., N.W., Washington, D.C. 20009. All correspondence will be sent to the first-named author unless otherwise specified. Papers that are not accompanied by a cover letter indicating that the paper is intended for publication will not be reviewed until such a statement is received. On a separate sheet include the names and mailing addresses of any authors who are not members of APA; they will be sent a complimentary copy of the issue in which their article appears.

Authors will be notified as soon as possible of the receipt of their paper and the number assigned to it. **This number must be included in all further correspondence.** It is imperative that the corresponding author of submitted papers notify the *Journal* of changes of address.

Annual Meeting Papers

The *Journal* has first refusal rights for numbered papers accepted for presentation at the Association's annual meetings, although not all papers can be published in the *Journal*. Authors of annual meeting papers should follow instructions they will receive in a letter from the Editor before the meeting. Annual meeting papers may be submitted for review before the meeting only if they are in **final form,** i.e., are ready for review. Authors must **not** submit their papers before the meeting if they expect any substantive revisions due to discussion at the meeting, further research, etc. These papers are subject to the same peer review criteria as other submissions. Authors who wish to submit their papers elsewhere must secure permission from the Editor. The *Journal* will assign its own number to each paper received for review; **this number must appear in any further communications about the paper.**

Length

The length of submitted material should not exceed the following specifications unless a special arrangement has been made with the Editor. Regular articles—3,800 words or the equivalent **(no more than 15 double-spaced pages, including references, tables, and figures).** Brief Communications—2,500 words **(no more than 10 double-spaced pages, including references, tables, and figures).** Clinical and Research Reports—1,000 words, 10 references, 1 table (no figures are used). Letters to the Editor—500 words, 5 references. The number of words, tables, and figures should be noted on the title page.

TYPES OF ARTICLES

Overviews

Overview articles attempt to bring together important relevant information on a topic of general interest to psychiatry. They are usually written at the invitation of the Editor; authors who have ideas for overview articles are advised to check with the Editor to ensure that a similar work is not in preparation. Overviews should not exceed 7,500 words **(no more than 25 double-spaced pages—including tables and figures—and 100 references).** All overviews, including those written by invitation, are given the same peer review received by other papers.

Regular Articles and Brief Communications

The primary difference between these two types of papers is length. The "brief communication" designation does not imply less sophisticated or complete work: it merely means that the content can be expressed within the upper limit of 2,500 words. There is no difference in the review procedure or scheduling of these articles. Authors who submit unnecessarily long articles with redundancies and loose writing style will be asked to shorten them, which can delay publication. Authors should choose their words carefully, avoiding lengthy introductions containing material that is common knowledge, summaries that merely repeat the results, unnecessary tables, figures, or references, etc. Single case reports should be submitted as Clinical and Research Reports.

Clinical and Research Reports

This section contains very brief articles (maximum of 1,000 words, 10 references, 1 table, and **no figures**) reporting new research findings, including preliminary data from pilot studies, and case reports that 1) describe new syndromes, 2) cast a new light on established ones, 3) indicate a new therapeutic procedure of potential value, or 4) describe adverse effects or previously unreported complications of drugs or therapeutic interventions. Because of the stringent criteria for this section, authors can expect more rapid publication than is possible in other sections. Submitted papers that substantially exceed the stated maximum length or contain figures will be returned to the author unreviewed.

Prompt Publication Policy

Articles submitted for prompt publication can be of either regular of Brief Communication length. (A "prompt publication policy" is automatically in effect for Clinical and Research Reports.) These papers are given priority in scheduling; however, authors should be aware that the minimum publication time is four months. Prompt publication papers must meet stringent criteria of originality and be of major immediate importance to the field. Authors must state their reasons for wanting rapid review in a cover letter to the Editor. It is important to think carefully about the nature of the paper before requesting prompt publication; a paper may be delayed if it is submitted inappropriately.

Other Sections

Letters to the Editor. Brief letters (maximum of 500 words and 5 references) will be considered if they include the notation "for publication" in the upper right corner. Letters critical of an article published in the *Journal* will automatically be sent to the authors for reply. Because of space limitations not all letters can be printed. The *Journal* is unable to notify authors of receipt of letters or to return those not published. All letters are subject to editing. Letters must be typed **double-spaced** throughout on letter-size bond paper; two copies are required. Letters that are not typed appropriately or do not conform to *Journal* reference style will be returned to the author for revision.

Book Reviews. Books for review may be sent directly to the Book Review Editor, Nancy C. Andreasen, M.D., University of Iowa College of Medicine, 500 Newton Rd., Iowa City, Iowa 52240. Book reviews are usually solicited by the Book Review Editor. Authors interested in reviewing a particular book are urged to contact the editorial office to see if the Book Review Editor wishes the book to be reviewed and to ascertain whether it has been previously assigned to another reviewer.

TYPING AND ARRANGING THE PAPER

All parts of the manuscript, including case reports, quotations, references, and tables, must be **double-spaced** throughout. All manuscripts must be typed in upper- and lowercase on one side only of 22 × 28 cm (8½ × 11 inches) **nonerasable** bond paper. All 4 margins must be 3¾ cm (1½ inches). The manuscript should be arranged in the following order, with each numbered item beginning a new page: 1) title page, 2) précis, 3) text, 4) references, 5) tables, 6) footnotes to text, and 7) figure captions. All pages must be numbered, with the title page as number 1. Please consult the following section on *Journal* style specifications for criteria for each part of the paper.

STYLE SPECIFICATIONS

Title Page

Title. The title should be informative but as brief as possible. Headline style (declarative sentences) should be avoided. Abbreviations and acronyms are rarely used in titles.

By-line. Authors named in the by-line should be limited to principal researchers and/or writers; collaborators can be acknowledged in a footnote. Degrees (other than honorary or undergraduate degrees) should be included after the authors' names.

Previous presentation. If the paper has been presented orally, please give the name of the meeting, the place, and inclusive dates.

Author affiliations. Provide the department, institution, city, and state where the work was done. If multiple locations and authors were involved, indicate in parentheses which authors were affiliated with each institution. Provide a full address for the author who is to receive reprint requests.

Acknowledgments. Acknowledgments should be in a separate paragraph on the title page. Grant support should include the full name of the granting agency as well as the grant number. Individual acknowledgments should be as brief as possible. Acknowledgments of companies that supplied drugs are used only in the case of experimental drugs or those unavailable in this country.

Other requirements. The number of words, tables, and figures should appear in the upper right corner and a phone number for the corresponding author in the lower right.

Précis

The précis should be up to 100 words for regular articles and Brief Communications. (No précis is used in the Clinical and Research Reports section.) The précis should be a single paragraph using complete, connected sentences, active verbs, and the third person. In most cases, the précis replaces a summary.

Text

Headings and subheadings should be inserted at reasonable intervals in all types of papers. Footnotes to text material should be typed on a separate page at the end of the manuscript. Summaries are rarely desirable, although a final "Comment" or "Conclusions" section may be used. The body of the paper should be written in the active voice and first person where appropriate.

Statistics. Authors should be sure that statistics used are

both necessary and appropriate. Statistical tests should be described and a reference citation given if the tests are not generally known. It is not sufficient to say "differences between the groups were significant." In cases of lengthy complicated analyses, the authors may summarize results and indicate that details are available from them on request.

Abbreviations. All abbreviations (other than those for metric units) should be explained the first time they are used. Idiosyncratic abbreviations should be avoided: overuse of abbreviations may hinder rather than facilitate readability.

Drugs. Generic rather than trade names of drugs should be used; trade names may be given parenthetically if necessary.

Units of measurement. All measurements should be in metric units; standard abbreviations are used.

References

References should be restricted to closely pertinent material: a complete review of the literature is rarely desirable. **Accuracy of citation is the author's responsibility.** References should conform exactly to the original spelling, accents, punctuation, etc. Authors should be sure that all references listed have been cited in text; no bibliographies can be used.

References are numbered and listed by their order of appearance in text; the text citation is followed by the appropriate reference number in parentheses. Do **not** arrange the list alphabetically.

Personal communications, unpublished manuscripts, manuscripts submitted but not yet accepted, and similar unpublished items should not appear in the reference list. Such citations may be noted in text or in a footnote. It is the author's responsibility to obtain permission to refer to another individual's unpublished observations. Manuscripts that are actually "in press" may be cited as such in the reference list; the name of the journal must be included.

Type references in the style shown below, **double-spaced throughout** (not just a line between references). List up to three authors; designate one or more authors past the third "et al." Abbreviations of journal names should conform to the style used in *Index Medicus*; journals not indexed there should not be abbreviated.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
3. Jones AB: Long-term administration of tricyclic antidepressants: three-year follow-up. Am J Psychiatry (in press)
4. Smythe JCW (ed): Psychiatry and Human Values. Springfield, Ill, Charles C Thomas, 1971
5. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968

Tables

Tables should be self-explanatory and should supplement rather than duplicate text. Authors may be asked to delete tables that present data which could be given succinctly in text or repeat information in the Results section. Tables are generally reserved for data presentation and not used as lists or charts. They should be **double-spaced** and no wider than 120 typewriter characters, including spaces. Consult recent issues of the *Journal* for table style. Please note that no vertical rules or internal horizontal rules are used. It is usually desirable to give both numbers and percentages where applicable. All units of measurement must be specified within the table. Metric measurements are used in tables and throughout the text. Each table should be identified numerically and include a concise but descriptive title.

Figures

Figures should be used only for data that cannot be adequately presented in text or tabular form. Figures should be submitted as glossy prints with one photocopy attached to each manuscript copy. The author's name and the title of the paper should appear on a gummed label affixed to the back of each glossy. All figures should be able to withstand reduction to about 8 cm (3¼ inches). Authors are urged to consider carefully the necessity of figures; they may be asked to delete figures that repeat information availabile in text. It is often advisable to obtain professional assistance in the preparation of figures.

PROCESSING OF ACCEPTED MANUSCRIPTS

Authors will be notified of acceptance of their papers; papers will then be edited and sent to the first-named (or corresponding) author for corrections and answers to editorial queries. No galley proofs are sent to authors, so the edited manuscript should be read with extreme care. Prompt return of edited manuscripts is essential. Authors who expect to be away from their offices for a long period or who change address after notification of acceptance should so inform the *Journal* office.

Manuscripts are accepted with the understanding that the Editor has the right to make revisions aimed at greater conciseness, clarity, and conformity with *Journal* style.

PERMISSION TO REPRINT

Written permission to reprint material published in the *Journal* must be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there is usually a charge for such permission, except in cases of nonprofit classroom or library reserve use by instructors and educational institutions, or of authors who wish to reprint their own material. Requests will be facilitated if they are accompanied by written permission from the author of the material.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about six weeks after publication of the article.

THE AMERICAN PSYCHIATRIC ASSOCIATION
1700 Eighteenth Street, N.W., Washington, D.C. 20009

OFFICERS 1980–1981

President: DONALD G. LANGSLEY
President-Elect: DANIEL X. FREEDMAN

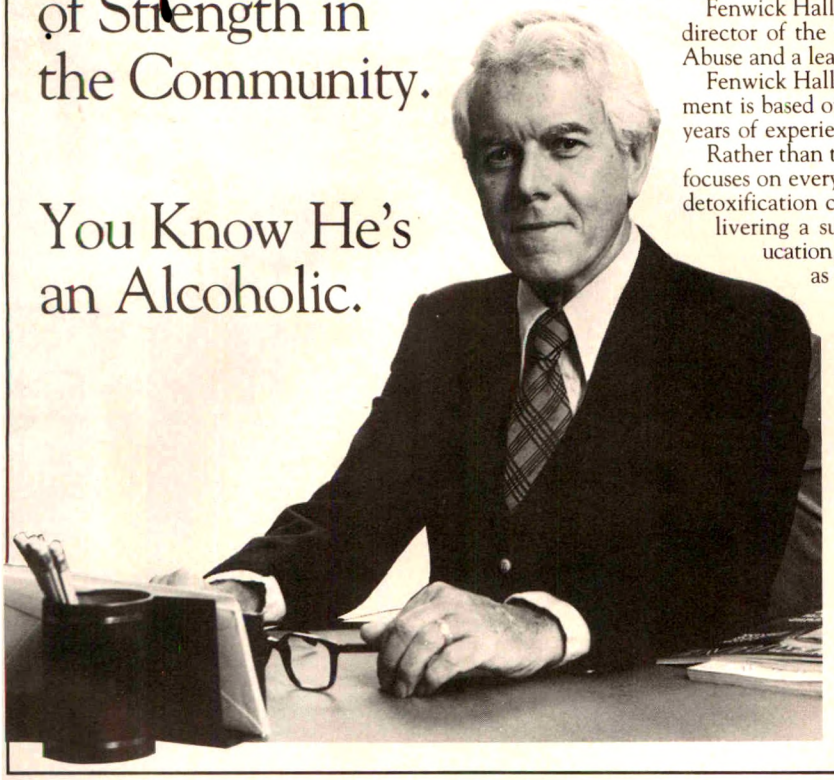
The October 1980 issue of

The American Journal of Psychiatry



will feature

- **Pathological Grief and the Activation of Latent Self-Images**
  By Mardi J. Horowitz, Nancy Wilner, Charles Marmar, and Janice Krupnick

- **Tardive Dyskinesia: Summary of a Task Force Report of the American Psychiatric Association**

Everyone Knows He's a Pillar of Strength in the Community.

You Know He's an Alcoholic.

You've seen what stress can do to people: everything from ulcers and high blood pressure, to a sense of isolation or a broken family.

You've also witnessed another consequence of stress: dependence on alcohol or drugs.

If some of your patients have drinking or drug problems, you should know about Fenwick Hall, a unique treatment facility near Charleston, S.C.

Fenwick Hall was established by Dr. Morris Chafetz, founding director of the National Institute on Alcoholism and Alcohol Abuse and a leading authority on alcohol and drug dependence.

Fenwick Hall's carefully designed, highly individualized treatment is based on the needs Dr. Chafetz perceived during his 25 years of experience with both patients and programs.

Rather than treating only symptoms, Fenwick Hall's approach focuses on every facet of the individual. In addition to complete detoxification capabilities and highly qualified professionals delivering a superior program of therapy, counseling and education, Fenwick Hall provides recreational options such as tennis courts, a sauna and whirlpool bath and an indoor swimming pool.

Occupying a recently restored 18th-century estate, Fenwick Hall offers unusually elegant accommodations and a tranquility conducive to the growth of self-awareness and the restoration of well-being.

When individuals leave Fenwick Hall, they are able to return to their careers and homes, fortified with healthier ways of coping with the stress and struggles of daily life.

For further information, please write for our color brochure, or call John Magill, Executive Director.

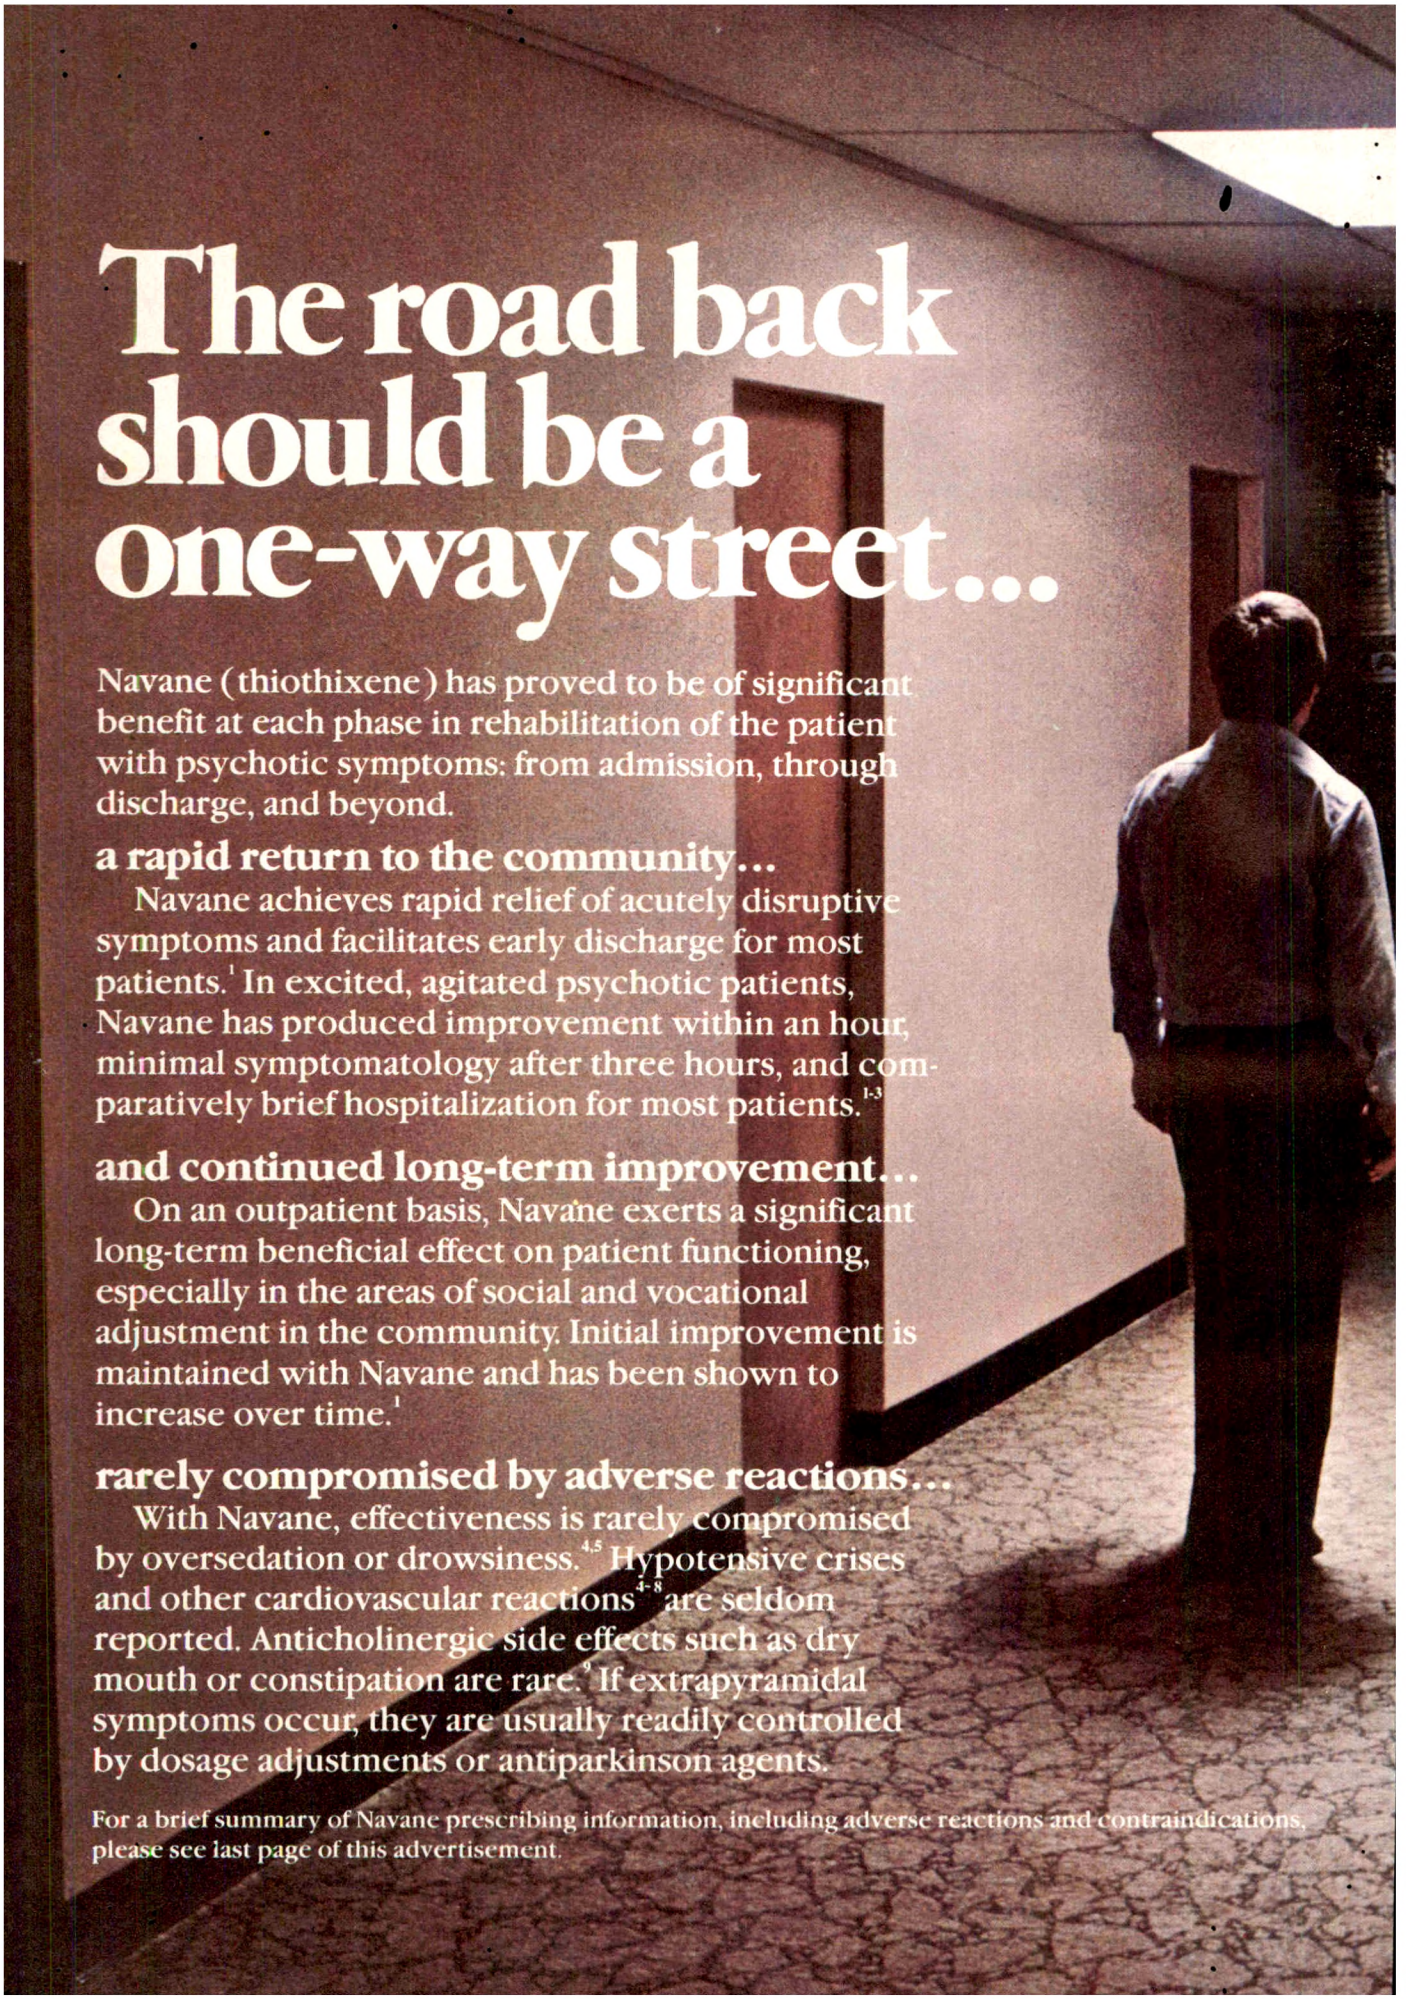
PSYCHOPHARMACOLOGY UPDATE

Jonathan O. Cole, M.D.

from

THE COLLAMORE PRESS



Medical Division of D.C. Heath and Company

For all practicing psychiatrists who wish to keep up to date on the uses of psychopharmacological agents and their potential side effects, this book offers a clear discussion of a range of available drugs. The information is practical and provides enough background for clinicians to practice psychopharmacology for the greatest benefit of patients. Newer agents such as lecithin, L-tryptophan, and fenfluramine are described. The book reviews treatment of such conditions as senile dementia and adult minimal brain dysfunction, and discusses such side effects of drugs as memory difficulties caused by tricyclic antidepressants, kidney changes due to lithium, and agranulocytosis resulting from antipsychotic drugs.

Table of contents: Part I. Drug Therapies: 1. Lithium Therapy: A Practical Review. 2. Tricyclic Antidepressant Blood Levels. 3. Drug Treatment of Anxiety. 4. Beta-Blocking Drugs in Psychiatry. 5. Drug Therapy of Adult Minimal Brain Dysfunction (MBD). 6. Fenfluramine. 7. Drugs and Senile Dementia. 8. Lecithin and Choline in Alzheimer Disease. Part II. Drug Side Effects: 9. Tardive Dyskinesia. 10. Agranulocytosis Revisited. 11. Lithium and the Kidney. 12. Memory Difficulty and Tricyclic Antidepressants.

208 pages **1980** **$14.95**
ISBN 0-669-03695-1 **LC 79-48064**

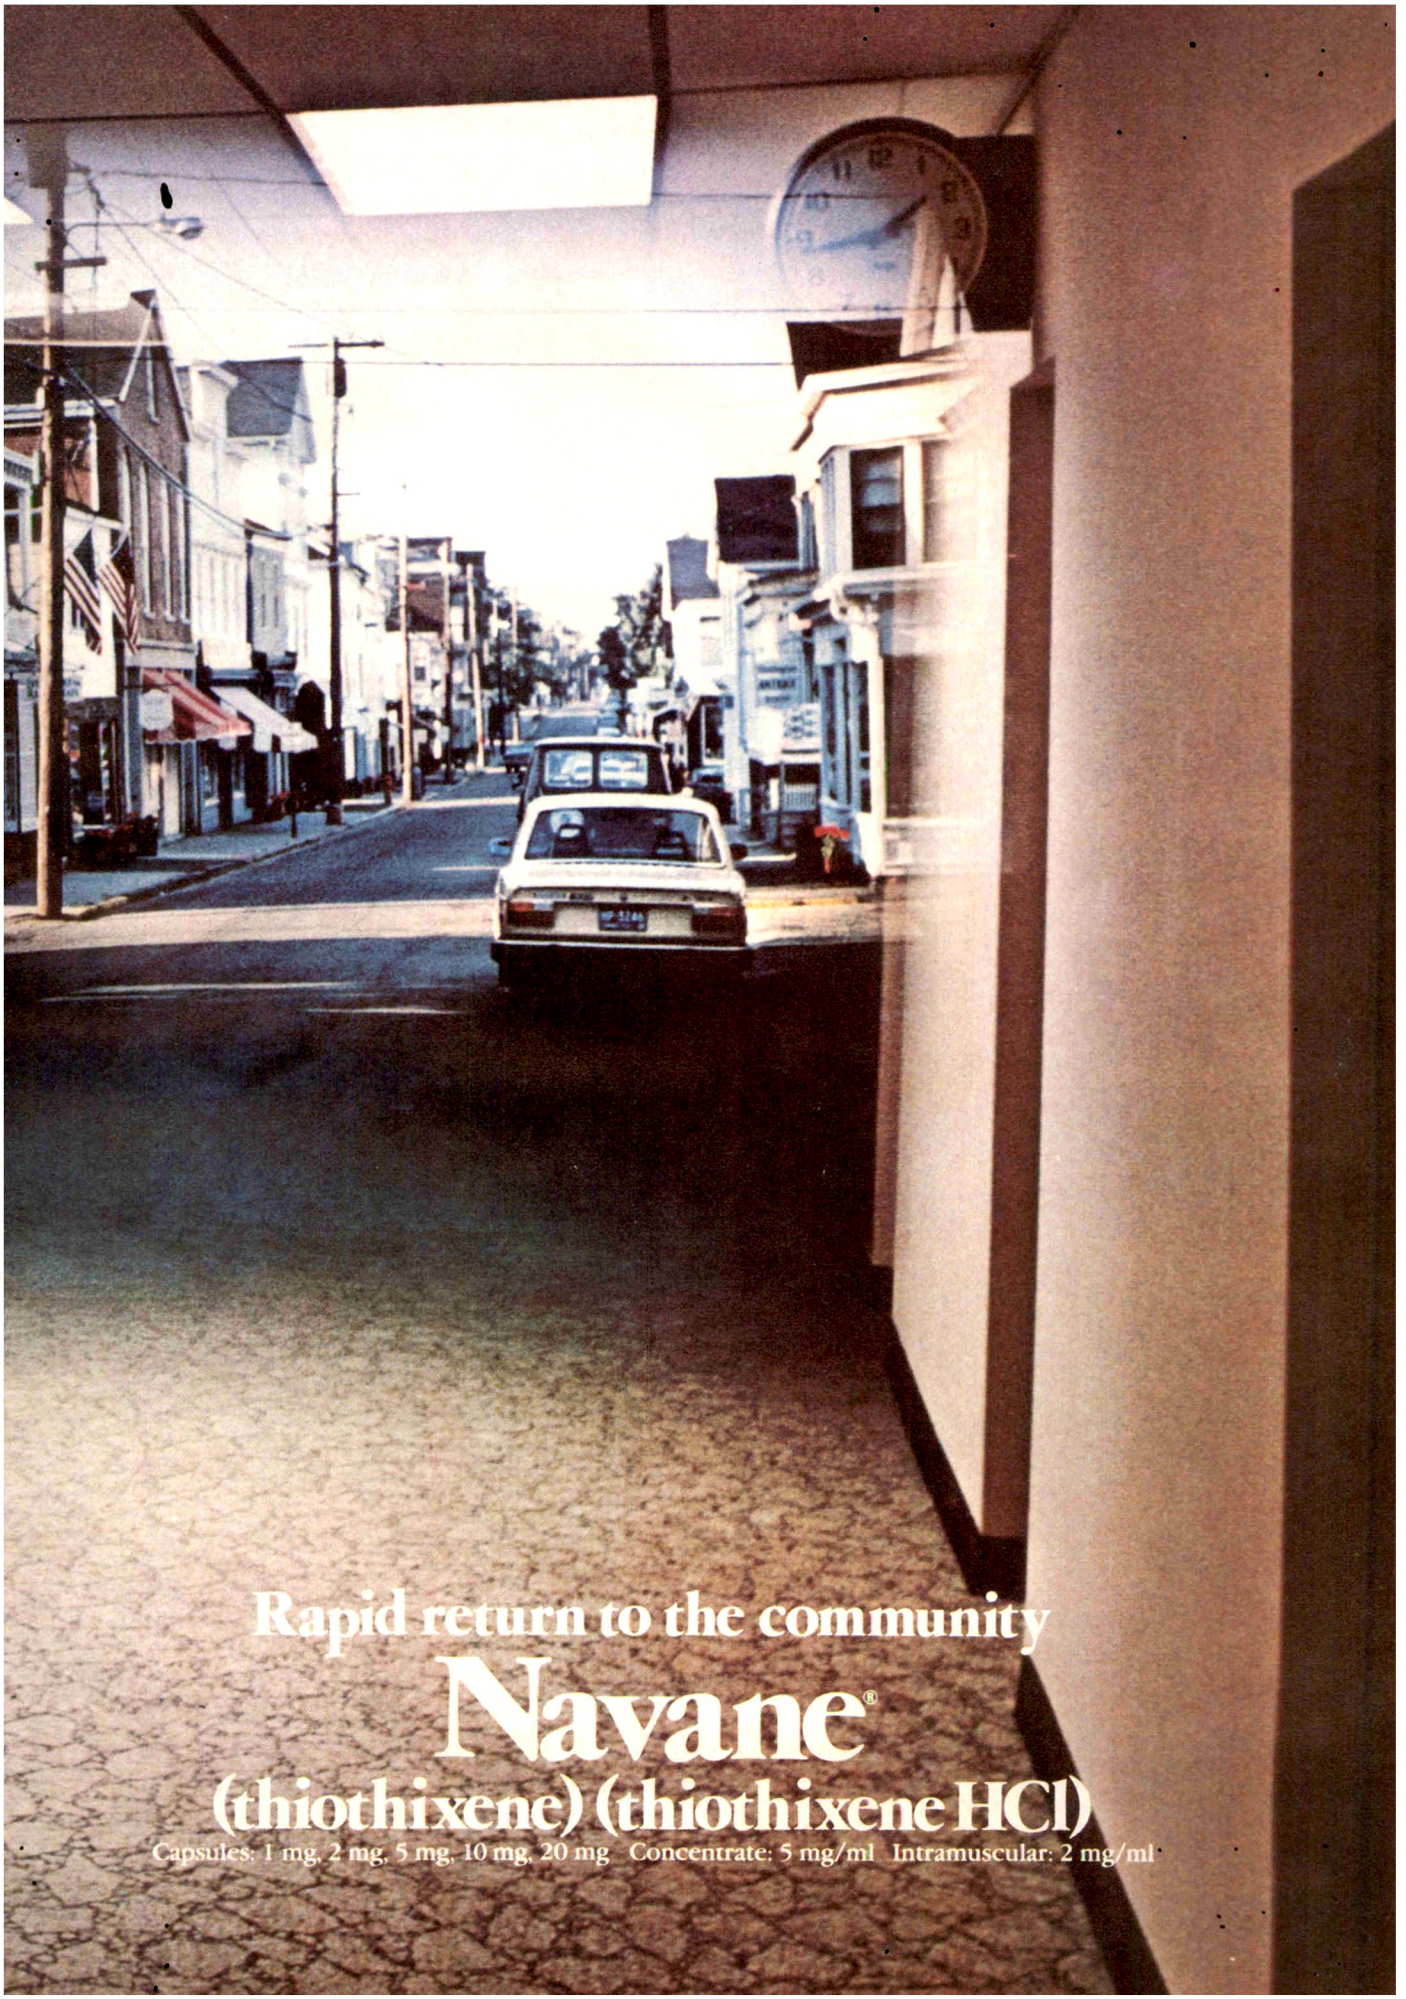
Send orders to The Collamore Press, D.C. Heath and Company, 125 Spring Street, Lexington, Massachusetts 02173.

The road back should be a one-way street...

Navane (thiothixene) has proved to be of significant benefit at each phase in rehabilitation of the patient with psychotic symptoms: from admission, through discharge, and beyond.

a rapid return to the community...

Navane achieves rapid relief of acutely disruptive symptoms and facilitates early discharge for most patients.[1] In excited, agitated psychotic patients, Navane has produced improvement within an hour, minimal symptomatology after three hours, and comparatively brief hospitalization for most patients.[1-3]



and continued long-term improvement...

On an outpatient basis, Navane exerts a significant long-term beneficial effect on patient functioning, especially in the areas of social and vocational adjustment in the community. Initial improvement is maintained with Navane and has been shown to increase over time.[1]

rarely compromised by adverse reactions...

With Navane, effectiveness is rarely compromised by oversedation or drowsiness.[4,5] Hypotensive crises and other cardiovascular reactions[4-8] are seldom reported. Anticholinergic side effects such as dry mouth or constipation are rare.[9] If extrapyramidal symptoms occur, they are usually readily controlled by dosage adjustments or antiparkinson agents.

For a brief summary of Navane prescribing information, including adverse reactions and contraindications, please see last page of this advertisement.

Rapid return to the community
Navane®
(thiothixene) (thiothixene HCl)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

Rapid return to the community

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg
(thiothixene hydrochloride) Concentrate: 5 mg/ml,
Intramuscular: 2 mg/ml

Contraindications. Navane (thiothixene) is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*–Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration of Navane to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children–The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration–As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., gluteus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution–For Intramuscular Use Only. Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane (thiothixene) Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate–In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Stimulants that may cause convulsions (e.g. picrotoxin or pentylenetetrazol) should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100, 1,000, and unit-dose pack of 100 (10 x 10's). Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100, 500, and unit-dose pack of 100 (10 x 10's).

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10 vials. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.

SURMONTIL®

(TRIMIPRAMINE MALEATE)

- **Proven efficacy in depression**[1,2]
- **Prompt relief of anxiety, even before peak antidepressant effects are noted**[3]
- **Insomnia relieved in some cases as soon as one week after treatment**[3]
- **Effective in single nighttime dosage after initial dosage titration**[3]
- **Low incidence of side effects**[4]

re prescribing, please see complete product information, a sum- of which follows:

TRAINDICATIONS: Contraindicated in cases of known hypersensi- to the drug, and during the acute recovery period after myocar- infarction. The possibility of cross-sensitivity to other dibenzaze- compounds should be kept in mind. Surmontil should not be in conjunction with drugs of the monoamine oxidase inhibitor OI) class. At least two weeks should elapse between cessation of apy with an MAOI and institution of therapy with Surmontil ipramine maleate).

NINGS: Children: This drug is not recommended for use in ren, since safety and effectiveness for the pediatric age group not been established. **Adults:** Use extreme caution in giving the to patients with evidence of cardiovascular disease. Caution is sed in patients with: increased intraocular pressure, history of ary retention, narrow-angle glaucoma, seizure disorder, hyper- idism, a need for thyroid medication. In patients receiving ethidine or similar agents, Surmontil may block the pharmaco- effects of these drugs. Warn patients that the drug may impair ental or physical abilities required for driving or performing potentially hazardous tasks.

CAUTIONS: Because of an inherently serious suicide potential, nonhospitalized severely depressed patient should be given the lest drug amount feasible. In schizophrenic patients, activation of sychosis may occur and require reduction of dosage or the addi- of a major tranquilizer to the medication schedule. Manic or manic episodes may occur, especially in patients with cyclic-type ders; Surmontil may have to be discontinued until the episode is ed and reinstituted, if required, at lower dosage. Limit concur- administration of Surmontil and electroconvulsive therapy to patients for whom it is essential. When possible, discontinue the for several days prior to elective surgery. The use of alcoholic drinks during therapy may provoke exaggerated response. Potentiation of effects has been reported when tricyclic antidepressants were administered with sympathomimetic amines, local decongestants, local anesthetics containing epinephrine, atropine, or drugs with an anticholinergic effect. Drugs having a parasympathetic effect, includ- ing tricyclic antidepressants, may alter ejaculatory response.

Usage in pregnancy: Pregnancy Category C. Surmontil has shown evi- dence of embryotoxicity and/or increased incidence of major anoma- lies in rats or rabbits at doses 20 times the human dose. There are no adequate and well-controlled studies in pregnant women. Surmontil should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

ADVERSE REACTIONS: When tricyclic antidepressants are used, each of the following adverse reactions must be considered, although some have not in fact been reported with Surmontil (trimipramine maleate).

Cardiovascular—Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric—Confusional states (especially in the elderly) with halluci- nations, disorientation, delusions; anxiety, restlessness, agitation; insomnia and nightmares; hypomania; exacerbation of psychosis.

Neurologic—Numbness, tingling, paresthesias of extremities; incoor- dination, ataxia, tremors; peripheral neuropathy; extrapyramidal symp- toms; seizures, alterations in EEG patterns; tinnitus.

Anticholinergic—Dry mouth and, rarely, associated sublingual adenitis; blurred vision, disturbances of accommodation, mydriasis, constipa- tion, paralytic ileus; urinary retention, delayed micturition, dilation of the urinary tract.

Allergic—Skin rash, petechiae, urticaria, itching, photosensitization, edema of face and tongue.

Hematologic—Bone-marrow depression including agranulocytosis, eosinophilia; purpura; thrombocytopenia. Leukocyte and differential counts should be performed in any patient who develops fever and sore throat during therapy; the drug should be discontinued if there is evidence of pathologic neutrophil depression.

Gastrointestinal—Nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine—Gynecomastia in the male; breast enlargement and galac- torrhea in the female; increased or decreased libido, impotence; tes- ticular swelling; elevation or depression of blood sugar levels.

Other—Jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency; drowsi- ness, dizziness, weakness, and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms—Though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

SUPPLIED: 25 mg in bottles of 100 opaque blue and yellow capsules, 50 mg in bottles of 100 opaque blue and orange capsules.

How do you choose a minor tranquilizer?

Wyeth Laboratories
Philadelphia, PA 19101
TM

Pharmacokinetics

Ativan (lorazepam) is eliminated more rapidly than other benzodiazepines; generates no clinically active metabolites. The half-life of free lorazepam is about 12 hours; steady-state blood levels are attained in 2-3 days. (Comparable data for diazepam: 20-50 hours and at least 7-10 days.) Ativan shows no evidence of accumulation, even when given in high doses for as long as 6 months. (The pharmacokinetic profile of a drug can define such characteristics as absorption, distribution, metabolism and elimination but cannot, at present, be directly related to its therapeutic effectiveness.)

Anxiety neuroses

In many nationwide studies involving thousands of patients with anxiety neuroses, Ativan (lorazepam) consistently provided significant relief of anxiety, tension, agitation and irritability as measured by standard Hamilton, Global (physician rated) and 35-Item (patient self-rated) scales.

Copyright © 1979, Wyeth Laboratories Div. of AHPC, N.Y., N.Y. All rights reserved.

They're all about the same, aren't they? Until recently, that seemed to sum up the prevalent attitude about the benzodiazepines. After all, they all work similarly and all are effective anxiolytics. With seven of these compounds now available, however, differences have begun to emerge. Foremost among them: different metabolic pathways, which distinguish the relatively short-acting Ativan (lorazepam) from long-acting diazepam, clorazepate and chlordiazepoxide. At the same time, your choice can be made with confidence in the clinical record of Ativan, which confirms its value in anxiety neuroses and in significant anxiety associated with functional or organic disorders, as well as in older patients.

Consider the record of Ativan:

Anxiety in cardiovascular disorders

Ativan (lorazepam) has been specifically evaluated and found effective in seven common protocol, double-blind studies involving 423 patients (211 on Ativan) whose anxiety was related to organic and functional cardiovascular disorders. The cardiovascular component has not, of course, been shown to be significantly benefited by such therapy.

Anxiety in gastrointestinal disorders

So far, nine common protocol, double-blind studies of Ativan have focused on anxious patients with functional or organic gastrointestinal complaints (457 patients, 234 on Ativan). Ativan was clearly effective in reducing the anxiety of these patients. The gastrointestinal component has not, of course, been shown to be significantly benefited by such therapy.

Anxiety in the aging patient

Because its simple metabolism is not readily impaired with advancing age, and accumulation is not likely to present a problem, Ativan is a good choice for older patients. Those who have trouble swallowing solid medication appreciate the small Ativan tablet, which is tasteless and disintegrates within seconds in water or fruit juice.

Ativan® (lorazepam) for Anxiety

See important information on following page.

Indications and Usage: Symptomatic relief of anxiety, tension, agitation, irritability and insomnia associated with anxiety neuroses and transient situational disturbances; anxiety associated with depressive symptoms and as a treatment of symptoms of anxiety if such symptoms are a significant feature of functional or organic disorders, particularly gastrointestinal or cardiovascular.

Effectiveness in long-term use, i.e., more than 4 months, has not been assessed by systematic clinical studies. Reassess periodically usefulness of the drug for the individual patient.

Contraindications: Known sensitivity to benzodiazepines or acute narrow-angle glaucoma.

Warnings: Not recommended in primary depressive disorders or psychoses. As with all CNS-acting drugs, warn patients on lorazepam not to operate machinery or motor vehicles, and of diminished tolerance for alcohol and other CNS depressants.

Physical and Psychological Dependence: Withdrawal symptoms like those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepines (including convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Addiction-prone individuals, e.g. drug addicts and alcoholics, should be under careful surveillance when on benzodiazepines because of their predisposition to habituation and dependence. Withdrawal symptoms have also been reported following abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months.

Precautions: In depression accompanying anxiety, consider possibility for suicide.

For elderly or debilitated patients, initial daily dosage should not exceed 2mg to avoid oversedation.

Terminate dosage gradually since abrupt withdrawal of any antianxiety agent may result in symptoms like those being treated: anxiety, agitation, irritability, tension, insomnia and occasional convulsions.

Observe usual precautions with impaired renal or hepatic function.

Where gastrointestinal or cardiovascular disorders coexist with anxiety, note that lorazepam has not been shown of significant benefit in treating gastrointestinal or cardiovascular component.

Esophageal dilation occurred in rats treated with lorazepam for more than 1 year at 5mg/kg/day. No effect dose was 1.25mg/kg/day (approximately 6 times the maximum human therapeutic dose of 10mg/day). Effect was reversible only when treatment was withdrawn within 2 months of first observation. Clinical significance is unknown; but use of lorazepam for prolonged periods and in geriatric patients requires caution and frequent monitoring for symptoms of upper G.I. disease.

Safety and effectiveness in children under 12 years have not been established.

ESSENTIAL LABORATORY TESTS: Some patients have developed leukopenia; some have had elevations of LDH. As with other benzodiazepines, periodic blood counts and liver function tests are recommended during long-term therapy.

CLINICALLY SIGNIFICANT DRUG INTERACTIONS: Benzodiazepines produce CNS depressant effects when administered with such medications as barbiturates or alcohol.

CARCINOGENESIS AND MUTAGENESIS: No evidence of carcinogenic potential emerged in rats during an 18-month study. No studies regarding mutagenesis have been performed.

PREGNANCY: Reproductive studies were performed in mice, rats, and 2 strains of rabbits. Occasional anomalies (reduction of tarsals, tibia, metatarsals, malrotated limbs, gastroschisis, malformed skull and microphthalmia) were seen in drug-treated rabbits without relationship to dosage. Although all these anomalies were not present in the concurrent control group, they have been reported to occur randomly in historical controls. At 40mg/kg and higher, there was evidence of fetal resorption and increased fetal loss in rabbits which was not seen at lower doses. Clinical significance of these findings is not known. However, increased risk of congenital malformations associated with use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during first trimester of pregnancy has been suggested in several studies. Because use of these drugs is rarely a matter of urgency, use of lorazepam during this period should almost always be avoided. Possibility that a woman of child-bearing potential may be pregnant at institution of therapy should be considered. Advise patients if they become pregnant to communicate with their physician about desirability of discontinuing the drug.

In humans, blood levels from umbilical cord blood indicate placental transfer of lorazepam and its glucuronide.

NURSING MOTHERS: It is not known if oral lorazepam is excreted in human milk like other benzodiazepines. As a general rule, nursing should not be undertaken while on a drug since many drugs are excreted in milk.

Adverse Reactions, if they occur, are usually observed at beginning of therapy and generally disappear on continued medication or on decreasing dose. In a sample of about 3,500 anxious patients, most frequent adverse reaction is sedation (15.9%), followed by dizziness (6.9%), weakness (4.2%) and unsteadiness (3.4%). Less frequent are disorientation, depression, nausea, change in appetite, headache, sleep disturbance, agitation, dermatological symptoms, eye function disturbance, various gastrointestinal symptoms and autonomic manifestations. Incidence of sedation and unsteadiness increased with age. Small decreases in blood pressure have been noted but are not clinically significant, probably being related to relief of anxiety.

Overdosage: In management of overdosage with any drug, bear in mind that multiple agents may have been taken. Manifestations of overdosage include somnolence, confusion and coma. Induce vomiting and/or undertake gastric lavage followed by general supportive care, monitoring of vital signs and close observation. Hypotension, though unlikely, usually may be controlled with Levarterenol Bitartrate Injection U.S.P. Usefulness of dialysis has not been determined.

Ativan® IV for (lorazepam) Anxiety

Dosage: **Individualize for maximum beneficial effects. Increase dose gradually when needed, giving higher evening dose before increasing daytime doses. Anxiety, usually 2-3mg/day given b.i.d. or t.i.d.; dosage may vary from 1 to 10mg/day in divided doses. For elderly or debilitated, initially 1-2mg/day; insomnia due to anxiety or transient situational stress, 2-4mg h.s.**

How Supplied: **0.5, 1.0 and 2.0mg tablets.**

No two children are alike.
That is why
No two programs in Devereux
Are the same.

The Foundation's nationwide therapeutic programs vary considerably to serve the needs of children, adolescents and young adults with learning disabilities, neurological impairment, mental retardation or emotional disturbance.

Devereux also offers specialty programs:

- **Hedges Treatment Center** — For young people who are not ready to utilize a conventional residential treatment approach but whose problems do not warrant psychiatric hospital attention.
- **Center for Autistic and Schizophrenic Children** — A comprehensive treatment program for children under ten years of age.
- **Career House** — For intellectually bright high school graduating seniors and post-high school youth with problems of underachievement and/or personal adjustment.

New! **COMPETITIVE BEHAVIORS OF OLYMPIC GYMNASTS** *by* **John H. Salmela.** The gymnasts' physical, mental, and emotional preparation; types of feedback; and stress control are among the topics covered. *'80, cloth-$19.75, paper-$14.50*

New! **THE EFFECT OF AIR IONIZATION, ELECTRIC FIELDS, ATMOSPHERICS AND OTHER ELECTRIC PHENOMENA ON MAN AND ANIMAL** *by* **Felix Gad Sulman.** Of special interest to psychiatrists are the chapters which cover such topics as stress reactions, biological rhythms, and effects related to psychiatry, neurology, crime, suicide, and age. *'80, cloth-$24.75, paper-$18.75*

New! **SEXUAL COUNSELING FOR OSTOMATES: A Resource Book for Health Care Professionals** *by* **Ellen A. Shipes** *and* **Sally T. Lehr.** The sexual needs and problems of ostomates are explored. *'80, $7.75, Lexotone*

New! **FACULTY DEVELOPMENT THROUGH WORKSHOPS** *by* **Carole J. Bland.** Practicality and specificity characterize this guide to planning, conducting, and evaluating faculty development workshops. *'80, cloth-$13.50, paper-$9.75*

New! **TRAINING OF THE DEVELOPMENTALLY HANDICAPPED ADULT: A Practical Guide to Habilitation** *by* **Roy I. Brown** *and* **E. Anne Hughson.** Functional assessment, learning techniques, and such managerial considerations as program structure, placement, follow-up, and administration are covered. *'80, $14.75*

New! **COMMUNICATIONS IN A HEALTH CARE SETTING** *edited by* **Myron G. Eisenberg, Judith Falconer** *and* **Lafaye C. Sutkin.** Included is information on general communication skills; legal implications; the medical record; audio-visual educational aids; special communication problems involving spinal cord injury patients, chronic pain patients, and children dying of cancer; and research. *'80, $19.75*

New! **THE BOTANY AND CHEMISTRY OF HALLUCINOGENS (2nd Ed.)** *by* **Richard Evans Schultes** *and* **Albert Hofmann.** Ethnobotanical, historical, pharmacological, and psychological aspects also receive attention. *'80, $28.75*

CHILD SEXUAL ABUSE: Analysis of a Family Therapy Approach *by* **Jerome A. Kroth.** The author reports on research into, recognition of, and treatment for intrafamilial child sexual abuse. *'79, $17.50*

PSYCHOLOGICAL TESTS AND SOCIAL WORK PRACTICE: An Introductory Guide *by* **Morton L. Arkava** *and* **Mark Snow.** This text focuses on the interpretation and utilization of psychological test information. *'78, cloth-$9.25, paper-$6.00*

ASSERTIVE TRAINING FOR WOMEN (2nd Ptg.) *by* **Susan M. Osborn** *and* **Gloria G. Harris.** Techniques which may be employed in a group approach to personal behavior change, such as behavior rehearsal, modeling, and cognitive restructuring, are described. *'78, cloth-$13.50, paper-$10.25*

PERSONALITY PROJECTION IN THE DRAWING OF THE HUMAN FIGURE: A Method of Personality Investigation (10th Ptg.) *by* **Karen Machover.** This original technique for human figure drawing analysis combines the psychology of expressive movement with a fresh approach to functional and symbolic significance. *'78, $11.00*

THE CARE AND MANAGEMENT OF THE SICK AND INCOMPETENT PHYSICIAN *by* **Robert C. Green, Jr., George J. Carroll** *and* **William D. Buxton.** Identification, management and prevention of physician incompetence are discussed. *'78, $11.00*

THE POWER OF POSITIVE REINFORCEMENT: A Handbook of Behavior Modification *by* **Judith Elbert Favell.** The author discusses specification of target behavior, selection of measurement techniques, and application of treatment. *'77, $12.50*

CLINICAL USE OF PSYCHOTHERAPEUTIC DRUGS (5th Ptg.) *by* **Leo E. Hollister.** Pharmacological properties, general principles of use, and side effects of drugs used in treating emotional disorders of adolescents and adults are discussed. *'77, $11.50*

RAPE INTERVENTION RESOURCE MANUAL *compiled and edited by* **Patrick Mills.** Psychological, medical, and legal aspects of sexual assault intervention are discussed. *'77, $18.75*

New! BURGLARY AND THEFT

By **John M. Macdonald,** *Univ. of Colorado School of Medicine, Denver. Contributions by* **C. Donald Brannan** *and* **Robert E. Nicoletti.** This is a comprehensive review of burglary and theft. It is based on the psychiatric evaluations of more than 100 offenders, augmented with more informal interviews with criminals, fences, and victims; on-the-street experience with burglary detectives; and the contributions of experts in the areas of evidence and investigation.

Ten chapters form the text. ***Burglary: The Billion Dollar Crime*** defines the crime and outlines its rate of occurrence. It details the burglar and his skills, the burglarization of a variety of targets, target selection, equipment, methods of entry, disposal of loot, and other topics. ***Theft*** explores vehicle theft, shoplifting, pocket picking, computer theft, and other types of theft. ***The Fence*** delineates fencing activities and classifies fences into categories. ***In Search of Causes*** analyzes crime in relation to sex, age, and race, and it explains motives, crime as punishment, the victim's role, and psychiatric disorders and crime. ***Victims of Burglary and Theft*** discusses victim-offender relationships, vulnerability, reactions, resistance, reporting, and victims in relation to the police.

False Reports of Burglary and Theft examines the forgetful, suspicious, or delusional complainant; motives for false reports; clues; checking for proof of purchase; and simulated burglary-homicide. ***Criminal Investigation*** outlines all aspects of burglary and theft investigation. ***Scientific Evidence*** explains the application of modern criminalistics in burglary and theft investigation. ***Criminal Interrogation*** offers data on preparation, the interviewing room, control of the interview, nonverbal communication, and details of the questioning itself. ***Prevention and Punishment*** outlines home and commercial security, prevention of shoplifting and vehicle theft, the victim in court, and punishment.

The author's thorough coverage of offender/victim psychology will provide much needed information for psychiatrists working with criminals, delinquents, and their victims. For those interested in doing further research, references are presented for each chapter. *'80, 292 pp., $19.75*

SURROUNDED BY A WALL OF INDIFFERENCE

'STELAZINE' HELPS FIND A WAY THROUGH

The schizophrenic patient is often withdrawn, aloof and emotionally unresponsive. For such patients, 'Stelazine' provides effective, unsurpassed control of these and other psychotic symptoms.

Also important, 'Stelazine' can help patients participate in your therapeutic programs. 'Stelazine' usually does not cause excessive sedation and offers the convenience of b.i.d. dosage.

In fact, no other antipsychotic agent has demonstrated significantly greater overall effectiveness and significantly fewer adverse effects than 'Stelazine'.

'Stelazine'. A first choice for therapy.

Before prescribing, see complete prescribing information in SK&F literature or PDR. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Generally avoid using in patients hypersensitive (e.g., blood dyscrasias, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Additive effect is possible with other C.N.S. depressants, including alcohol.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudoparkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions, peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

STELAZINE®

TABLETS: 5 and 10 mg.

brand of
TRIFLUOPERAZINE HCl

A First Choice for Therapy

breaking
through

In marked agitation with depression symptomatic relief may make the patient more accessible and responsive.

Rapid relief of marked agitation in many patients
The tranquilizer component alleviates symptoms of agitation and anxiety within a few days, without apparent dulling of mental acuity. Hypnotic effects from the tranquilizer component appear to be minimal, particularly in patients permitted to remain active. However, TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks.

Highly effective antidepressant action
The antidepressant component relieves symptoms of depression such as poor concentration and feelings of hopelessness as well as early morning awakening; adequate relief of symptoms may take a few weeks or even longer.

Helps break barriers to psychotherapy
As symptoms are relieved, many patients often communicate more effectively, become more cooperative, and are able to return to normal daily activities.

More prescribing convenience
There are now *five* tablet strengths of TRIAVIL for ease of dosage adjustment. For many patients with agitation and depression, you can now initiate therapy with one TRIAVIL® 4-50, containing 4 mg perphenazine and 50 mg amitriptyline HCl, b.i.d. The regimen is simple, economical, and may well enhance patient compliance.

Treatment with TRIAVIL—a balanced view:
TRIAVIL is contraindicated in CNS depression from drugs, in the presence of evidence of bone marrow depression, and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. TRIAVIL may impair mental and/or physical abilities required for performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to overdosage of other drugs or mask other disorders. The possibility of suicide in depressed patients remains until significant remission occurs. Such patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

For marked agitation with depression

dual-action® **Triavil**

containing perphenazine and amitriptyline HCl

MSD
MERCK SHARP & DOHME

Copyright © 1979 by Merck & Co., Inc.

Please see following page for a brief summary of prescribing information.

More dosage strengths
than any other formulation containing
a tranquilizer and an antidepressant

dual-action Triavil®

containing perphenazine and amitriptyline HCl

Available:
TRIAVIL® 2-25: Each tablet contains
2 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 2-10: Each tablet contains
2 mg perphenazine and 10 mg amitriptyline HCl.
TRIAVIL® 4-50: Each tablet contains
4 mg perphenazine and 50 mg amitriptyline HCl.
TRIAVIL® 4-25: Each tablet contains
4 mg perphenazine and 25 mg amitriptyline HCl.
TRIAVIL® 4-10: Each tablet contains
4 mg perphenazine and 10 mg amitriptyline HCl.

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); evidence of bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with TRIAVIL. Therapy should then be initiated cautiously with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given concomitantly with guanethidine or similarly acting compounds since TRIAVIL may block the antihypertensive action of such compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. Dosage of anticonvulsive agents may have to be increased. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time, particularly in high doses. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. In patients who use alcohol excessively, potentiation may increase the danger inherent in any suicide attempt or overdosage. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of some untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides. There is sufficient experimental evidence to conclude that chronic administration of antipsychotic drugs which increase prolactin secretion has the potential to induce mammary neoplasms in rodents under the appropriate conditions. There are recognized differences in the physiological role of prolactin between rodents and humans. Since there are, at present, no adequate epidemiological studies, the relevance to human mammary cancer risk from prolonged exposure to perphenazine and other antipsychotic drugs is not known.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.
Perphenazine: Extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) have been reported and can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw. Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. Fine vermicular movements of the tongue may be an early sign of the syndrome. The full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; other adverse reactions reported with various phenothiazine compounds, but not with perphenazine, include grand mal convulsions, cerebral edema, polyphagia, pigmentary retinopathy, photophobia, skin pigmentation, and failure of ejaculation.

The phenothiazine compounds have produced blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); and liver damage (jaundice, biliary stasis).

Pigmentation of the cornea and lens has been reported to occur after long-term administration of some phenothiazines. Although it has not been reported in patients receiving TRIAVIL, the possibility that it might occur should be considered.

Hypnotic effects, lassitude, muscle weakness, and mild insomnia have also been reported.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs and must be considered when amitriptyline is administered. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; increased intraocular pressure; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness, weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

The Brown Schools: Specialists in Residential Treatment

Residential treatment has become highly specialized in the field of mental health. It is a specific treatment modality for those who need a totally planned and structured environment.

The Brown Schools has developed a wide range of professional services that can be utilized to implement an individually planned residential treatment program. The degree of structure and protection, the intensity of therapy, the methods of education and training are controlled and modified with the resident's changing needs.

Professionals in the areas of psychiatry, psychology, nursing, social work, education, prevocational training, speech pathology, and recreation have developed expertise in the specific area of residential treatment. Each service area is designed as a component of an integrated therapeutic milieu.

The three residential treatment centers of The Brown Schools provide complete programming for those in need of twenty-four hour care. Services are available for children, adolescents, and adults with emotional disturbance, mental retardation, and neurological impairment. Two small group homes in Austin provide for reintegration into the community and complement the services offered in the other centers. For information, write:

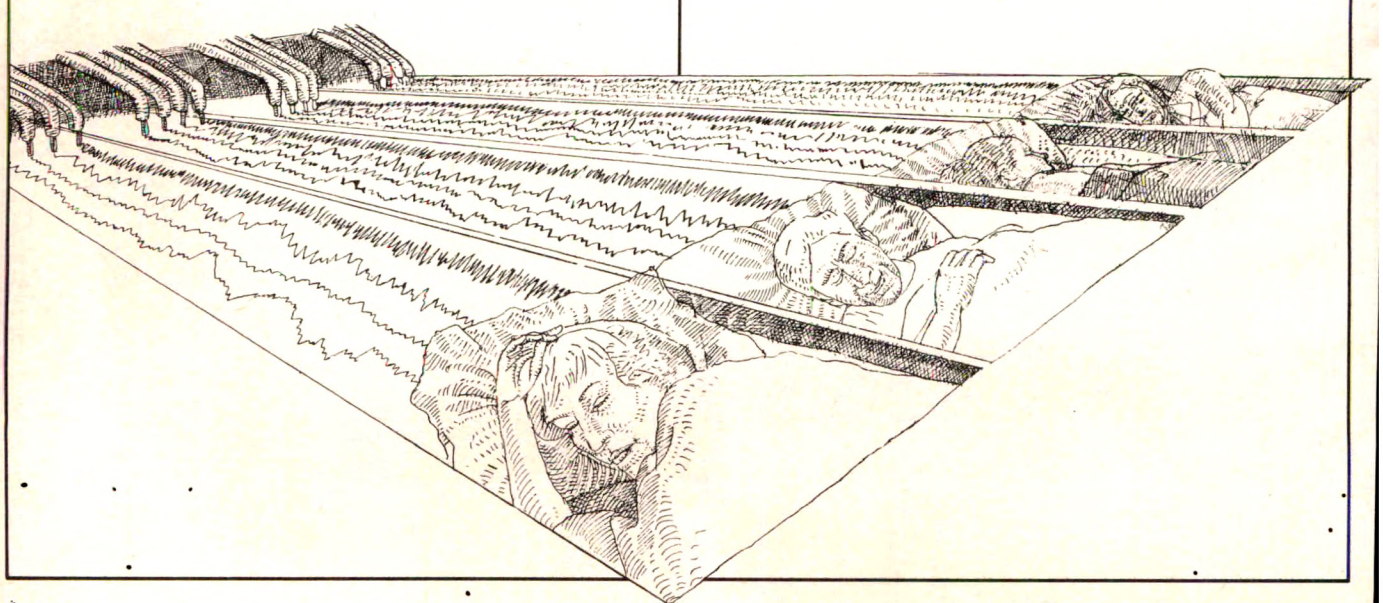
DALMANE
(flurazepam HCl/Roche

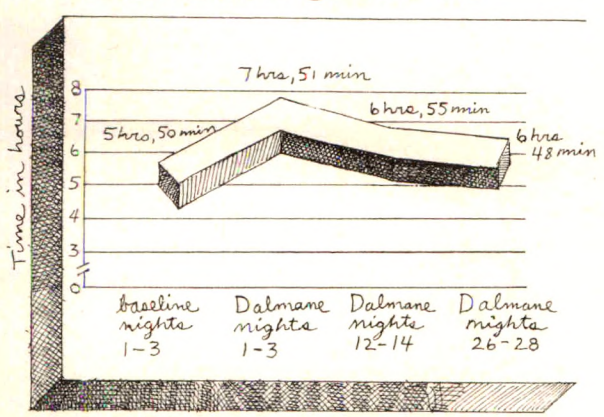


MORE POLYGRAPHIC EVIDENCE

Sleep research laboratory testing of insomnia patients for 995 subject nights demonstrates efficacy of Dalmane (flurazepam HCl/Roche)[1]

In 14 separate studies, subjects given Dalmane were monitored with polygraphic recordings for a total of 995 nights, objectively demonstrating the efficacy of Dalmane.

Efficacy from the first night through 28 nights, without need to increase dosage



Dalmane (flurazepam HCl/Roche) is the only sleep medication objectively proven effective through 28 consecutive nights of administration in two separate studies in the sleep research laboratory.[2-4] The prolonged use of Dalmane is seldom necessary; should it be, appropriate patient evaluations such as periodic blood counts and liver and kidney function tests are recommended.

OFFERS

OF EFFICACY FOR INSOMNIA

Dalmane® (flurazepam HCl/Roche) improved sleep during short, intermediate and longer-term use

Improvement shown represents mean improvement, in hours, of total sleep time. n=5

Adapted from Dement WC, *et al: Behav Med* 5:25-31, Oct 1978

Since most insomnia is transitory in nature, initiate therapy at the lowest effective dose for the shortest time advisable to achieve a predetermined therapeutic goal.

References:
1. Data on file, Medical Department, Hoffmann-La Roche Inc., Nutley NJ
2. Kales A, *et al: Clin Pharmacol Ther* 19: 576-583, May 1976
3. Dement WC, *et al: Behav Med* 5: 25-31, Oct 1978
4. Kales A, *et al: Clin Pharmacol Ther* 18: 356-363, Sep 1975

Clinical documentation of efficacy in 4950 patients with insomnia[1]

Dalmane (flurazepam HCl/Roche) efficacy was evaluated in 18 clinical studies. These included paired-night, double-blind crossover, double-blind comparison and patient preference studies. Results of these studies demonstrated and confirmed the effectiveness of Dalmane.

Periodic evaluation of patient's sleep habits may help prevent subsequent insomnia

Should insomnia recur, the patient may need guidance in setting up a regular sleep program. This may include establishment of a regular bedtime hour, taking a warm bath prior to retiring and avoidance of alcohol, stimulants or heavy meals late in the evening.

UNMATCHED PROOF, UNMATCHED EFFICACY

Please see summary of product information on following page.

ROCHE®

Protocol for insomnia management

☐ Treat physical and/or psychological factors that may underlie an inability to sleep.

☐ Thoroughly question and evaluate new patients who specifically request sleep medications.

☐ Consider other medications the patient may be taking (including alcoholic beverages) and be aware of possible drug interactions.

☐ Select a sleep medication with objectively *documented* proof of efficacy and a wide margin of safety.

☐ Initiate treatment at the lowest effective dose for the period of time deemed necessary *to achieve a reasonable therapeutic goal.*

☐ Monitor response to therapy and, based upon patient reassessment, determine need for continuing medication on an individual basis.

☐ Advise patients who ingest alcoholic beverages or other CNS depressants against doing so while on sleep medication. CNS stimulants such as caffeine should also be discontinued.

☐ Caution patients against engaging in hazardous occupations requiring complete mental alertness such as operating machinery or driving a motor vehicle shortly after ingesting the drug. In addition, as with all CNS depressants, patients may have reduced motor performance while on hypnotic therapy and should be advised accordingly.

☐ Avoid prescribing for suicidal or dependency-prone individuals whose histories indicate an inability to handle any psychoactive substances including alcohol.

Now available from Roche—important guidance for your patients with insomnia.

DALMANE® (IV)
flurazepam HCl/Roche

One 15-mg capsule *h.s.*—recommended initial dosage for elderly or debilitated patients.
One 30-mg capsule *h.s.*—usual adult dosage
(15 mg may suffice in some patients).

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Objective sleep laboratory data have shown effectiveness for at least 28 consecutive nights of administration. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.
Contraindications: Known hypersensitivity to flurazepam HCl.
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).

Usage in Pregnancy: **Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane, a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.
Precautions: In elderly and debilitated patients, it is recommended that the dosage be limited to 15 mg to reduce risk of oversedation, dizziness, confusion and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies, or with impaired renal or hepatic function. Periodic blood counts and liver and kidney function tests are advised during repeated therapy.
Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.
Dosage: Individualize for maximum beneficial effect.
Adults: 30 mg usual dosage; 15 mg may suffice in some patients.
Elderly or debilitated patients: 15 mg recommended initially until response is determined.
Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

ROCHE PRODUCTS INC.
Manati, Puerto Rico 00701

ROCHE®

Introducing...

Navane®
(thiothixene HCl)
Intramuscular
For Injection
5 mg/ml

new potency for rapid control of acute psychiatric emergencies

Now, Navane Intramuscular 5 mg per ml provides a more concentrate dosage form for rapid control of severely disturbed behavior associated with acute psychosis. Navane Intramuscular, in carefully monitored doses, "...can produce significant improvement within hours and increase the accessibility of these [acutely disturbed] patients to more gradual methods of pharmacologic treatment as well as to socio-environmental intervention and psychotherapy."[1]

Rapid tranquilization usually can be achieved without excessive sedation.[1] Clinically significant hypotension, often seen with other injectable antipsychotic agents, is rare with Navane Intramuscular therapy.[1-3] If extrapyramidal symptoms occur, they are usually readily controlled by dosage adjustment or antiparkinson agents.

ROERIG Pfizer
A division of Pfizer Pharmaceuticals
New York, New York 10017

For a brief summary of Navane prescribing information, including adverse reactions and contraindications, please see the following page of this advertisement.

Navane® (thiothixene) (thiothixene hydrochloride)

Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg Concentrate: 5 mg/ml Intramuscular: 2 mg/ml, 5 mg/ml

BRIEF SUMMARY OF PRESCRIBING INFORMATION
Navane® (thiothixene)
Capsules: 1 mg, 2 mg, 5 mg, 10 mg, 20 mg (thiothixene hydrochloride) Concentrate: 5 mg/ml, Intramuscular: 2 mg/ml, 5 mg/ml

Contraindications. Navane (thiothixene) is contraindicated in patients with circulatory collapse, comatose states, central nervous system depression due to any cause, and blood dyscrasias. Navane is contraindicated in individuals who have shown hypersensitivity to the drug. It is not known whether there is a cross-sensitivity between the thioxanthenes and the phenothiazine derivatives, but this possibility should be considered.

Warnings. *Usage in Pregnancy*– Safe use of Navane during pregnancy has not been established. Therefore, this drug should be given to pregnant patients only when, in the judgment of the physician, the expected benefits from the treatment exceed the possible risks to mother and fetus. Animal reproduction studies and clinical experience to date have not demonstrated any teratogenic effects.

In the animal reproduction studies with Navane, there was some decrease in conception rate and litter size, and an increase in resorption rate in rats and rabbits, changes which have been similarly reported with other psychotropic agents. After repeated oral administration of Navane to rats (5 to 15 mg/kg/day), rabbits (3 to 50 mg/kg/day), and monkeys (1 to 3 mg/kg/day) before and during gestation, no teratogenic effects were seen. (See Precautions.)

Usage in Children– The use of Navane in children under 12 years of age is not recommended because safety and efficacy in the pediatric age group have not been established.

As is true with many CNS drugs, Navane may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks such as driving a car or operating machinery, especially during the first few days of therapy. Therefore, the patient should be cautioned accordingly.

As in the case of other CNS-acting drugs, patients receiving Navane should be cautioned about the possible additive effects (which may include hypotension) with CNS depressants and with alcohol.

Precautions. An antiemetic effect was observed in animal studies with Navane; since this effect may also occur in man, it is possible that Navane may mask signs of overdosage of toxic drugs and may obscure conditions such as intestinal obstruction and brain tumor.

In consideration of the known capability of Navane and certain other psychotropic drugs to precipitate convulsions, extreme caution should be used in patients with a history of convulsive disorders or those in a state of alcohol withdrawal since it may lower the convulsive threshold. Although Navane potentiates the actions of the barbiturates, the dosage of the anticonvulsant therapy should not be reduced when Navane is administered concurrently.

Caution as well as careful adjustment of the dosage is indicated when Navane is used in conjunction with other CNS depressants other than anticonvulsant drugs.

Though exhibiting rather weak anticholinergic properties, Navane should be used with caution in patients who are known or suspected to have glaucoma, or who might be exposed to extreme heat, or who are receiving atropine or related drugs.

Use with caution in patients with cardiovascular disease.

Also, careful observation should be made for pigmentary retinopathy, and lenticular pigmentation (fine lenticular pigmentation has been noted in a small number of patients treated with Navane for prolonged periods). Blood dyscrasias (agranulocytosis, pancytopenia, thrombocytopenic purpura), and liver damage (jaundice, biliary stasis) have been reported with related drugs.

Undue exposure to sunlight should be avoided. Photosensitive reactions have been reported in patients on Navane.

Intramuscular Administration– As with all intramuscular preparations, Navane Intramuscular should be injected well within the body of a relatively large muscle. The preferred sites are the upper outer quadrant of the buttock (i.e., glutеus maximus) and the mid-lateral thigh.

The deltoid area should be used only if well developed, such as in certain adults and older children, and then only with caution to avoid radial nerve injury. Intramuscular injections should not be made into the lower and mid-thirds of the upper arm. As with all intramuscular injections, aspiration is necessary to help avoid inadvertent injection into a blood vessel.

Adverse Reactions. *Note:* Not all of the following adverse reactions have been reported with Navane (thiothixene). However, since Navane has certain chemical and pharmacologic similarities to the phenothiazines, all of the known side effects and toxicity associated with phenothiazine therapy should be borne in mind when Navane is used.

Cardiovascular effects: Tachycardia, hypotension, lightheadedness, and syncope. In the event hypotension occurs, epinephrine should not be used as a pressor agent since a paradoxical further lowering of blood pressure may result. Nonspecific EKG changes have been observed in some patients receiving Navane. These changes are usually reversible and frequently disappear on continued Navane therapy. The incidence of these changes is lower than that observed with some phenothiazines. The clinical significance of these changes is not known.

CNS effects: Drowsiness, usually mild, may occur although it usually subsides with continuation of Navane therapy. The incidence of sedation appears similar to that of the piperazine group of phenothiazines, but less than that of certain aliphatic phenothiazines. Restlessness, agitation and insomnia have been noted with Navane (thiothixene). Seizures and paradoxical exacerbation of psychotic symptoms have occurred with Navane infrequently.

Hyperreflexia has been reported in infants delivered from mothers having received structurally related drugs.

In addition, phenothiazine derivatives have been associated with cerebral edema and cerebrospinal fluid abnormalities.

Extrapyramidal symptoms, such as pseudo-parkinsonism, akathisia, and dystonia have been reported. Management of these extrapyramidal symptoms depends upon the type and severity. Rapid relief of acute symptoms may require the use of an injectable antiparkinson agent. More slowly emerging symptoms may be managed by reducing the dosage of Navane and/or administering an oral antiparkinson agent.

Persistent Tardive Dyskinesia: As with all antipsychotic agents tardive dyskinesia may appear in some patients on long term therapy or may occur after drug therapy has been discontinued. The risk seems to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities.

There is no known effective treatment for tardive dyskinesia: antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear.

Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked.

It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time, the syndrome may not develop.

Hepatic effects: Elevations of serum transaminase and alkaline phosphatase, usually transient, have been infrequently observed in some patients. No clinically confirmed cases of jaundice attributable to Navane have been reported.

Hematologic effects: As is true with certain other psychotropic drugs, leukopenia and leukocytosis, which are usually transient, can occur occasionally with Navane. Other antipsychotic drugs have been associated with agranulocytosis, eosinophilia, hemolytic anemia, thrombocytopenia and pancytopenia.

Allergic reactions: Rash, pruritus, urticaria, photosensitivity and rare cases of anaphylaxis have been reported with Navane. Undue exposure to sunlight should be avoided. Although not experienced with Navane, exfoliative dermatitis and contact dermatitis (in nursing personnel) have been reported with certain phenothiazines.

Endocrine disorders: Lactation, moderate breast enlargement and amenorrhea have occurred in a small percentage of females receiving Navane. If persistent, this may necessitate a reduction in dosage or the discontinuation of therapy. Phenothiazines have been associated with false positive pregnancy tests, gynecomastia, hypoglycemia, hyperglycemia, and glycosuria.

Autonomic effects: Dry mouth, blurred vision, nasal congestion, constipation, increased sweating, increased salivation, and impotence have occurred infrequently with Navane therapy. Phenothiazines have been associated with miosis, mydriasis, and adynamic ileus.

Other adverse reactions: Hyperpyrexia, anorexia, nausea, vomiting, diarrhea, increase in appetite and weight, weakness or fatigue, polydipsia and peripheral edema.

Although not reported with Navane, evidence indicates there is a relationship between phenothiazine therapy and the occurrence of a systemic lupus erythematosus-like syndrome.

NOTE: Sudden deaths have occasionally been reported in patients who have received certain phenothiazine derivatives. In some cases the cause of death was apparently cardiac arrest or asphyxia due to failure of the cough reflex. In others, the cause could not be determined nor could it be established that death was due to phenothiazine administration.

Dosage and Administration. Dosage of Navane should be individually adjusted depending on the chronicity and severity of the condition. In general, small doses should be used initially and gradually increased to the optimal effective level, based on patient response.

Some patients have been successfully maintained on once-a-day Navane therapy.

Usage in children under 12 years of age is not recommended because safe conditions for its use have not been established.

Navane Intramuscular Solution; Navane For Injection– Where more rapid control and treatment of acute behavior is desirable, the intramuscular form of Navane may be indicated. It is also of benefit where the very nature of the patient's symptomatology, whether acute or chronic, renders oral administration impractical or even impossible.

For treatment of acute symptomatology or in patients unable or unwilling to take oral medication, the usual dose is 4 mg of Navane Intramuscular administered 2 to 4 times daily. Dosage may be increased or decreased depending on response. Most patients are controlled on a total daily dosage of 16 to 20 mg. The maximum recommended dosage is 30 mg/day. An oral form should supplant the injectable form as soon as possible. It may be necessary to adjust the dosage when changing from the intramuscular to oral dosage forms. Dosage recommendations for Navane (thiothixene) Capsules and Concentrate appear in the following paragraphs.

Navane Capsules; Navane Concentrate– In milder conditions, an initial dose of 2 mg three times daily. If indicated, a subsequent increase to 15 mg/day total daily dose is often effective.

In more severe conditions, an initial dose of 5 mg twice daily.

The usual optimal dose is 20 to 30 mg daily. If indicated, an increase to 60 mg/day total daily dose is often effective. Exceeding a total daily dose of 60 mg rarely increases the beneficial response.

Overdosage. Manifestations include muscular twitching, drowsiness, and dizziness. Symptoms of gross overdosage may include CNS depression, rigidity, weakness, torticollis, tremor, salivation, dysphagia, hypotension, disturbances of gait, or coma.

Treatment: Essentially symptomatic and supportive. For Navane oral, early gastric lavage is helpful. For Navane oral and Intramuscular, keep patient under careful observation and maintain an open airway, since involvement of the extrapyramidal system may produce dysphagia and respiratory difficulty in severe overdosage. If hypotension occurs, the standard measures for managing circulatory shock should be used (I.V. fluids and/or vasoconstrictors).

If a vasoconstrictor is needed, levarterenol and phenylephrine are the most suitable drugs. Other pressor agents, including epinephrine, are not recommended, since phenothiazine derivatives may reverse the usual pressor action of these agents and cause further lowering of blood pressure.

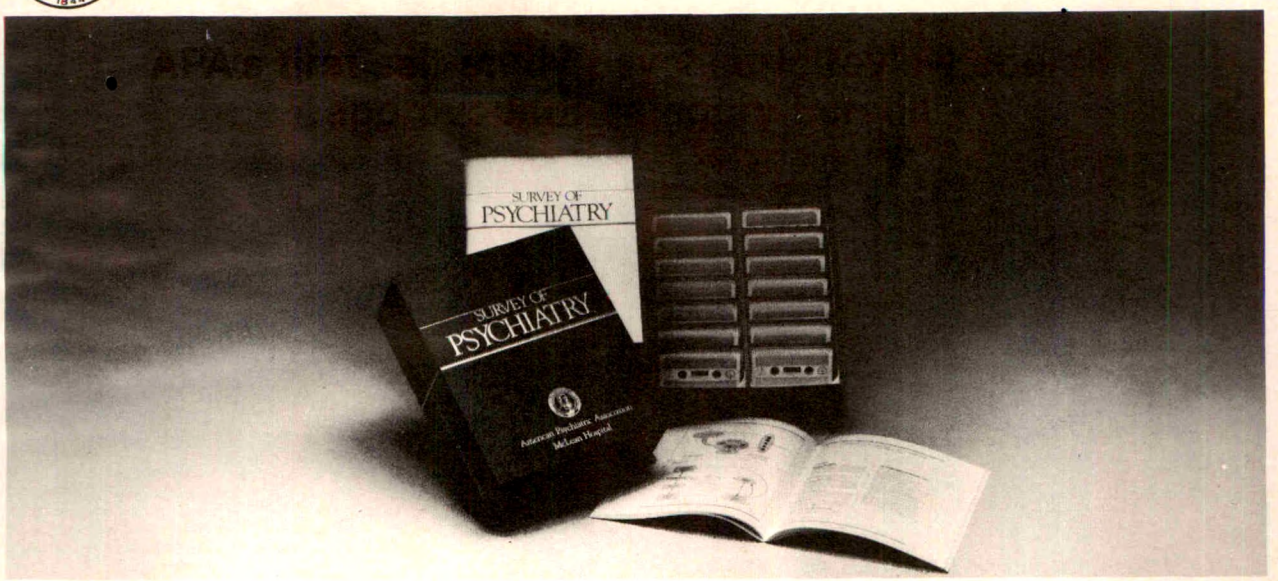
If CNS depression is present, recommended stimulants include amphetamine, dextroamphetamine, or caffeine and sodium benzoate. Stimulants that may cause convulsions (e.g. picrotoxin or pentylenetetrazol) should be avoided. Extrapyramidal symptoms may be treated with antiparkinson drugs.

There are no data on the use of peritoneal or hemodialysis, but they are known to be of little value in phenothiazine intoxication.

How Supplied. Navane (thiothixene) is available as capsules containing 1 mg, 2 mg, 5 mg, and 10 mg of thiothixene in bottles of 100, 1,000, and unit-dose pack of 100 (10 x 10's). Navane is also available as capsules containing 20 mg of thiothixene in bottles of 100, 500, and unit-dose pack of 100 (10 x 10's).

Navane (thiothixene hydrochloride) Concentrate is available in 120 ml (4 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, 5 mg, 6 mg, 8 mg, and 10 mg, and in 30 ml (1 oz.) bottles with an accompanying dropper calibrated at 2 mg, 4 mg, and 5 mg. Each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene. Contains alcohol, U.S.P. 7.0% v/v (small loss unavoidable).

Navane (thiothixene hydrochloride) Intramuscular solution is available in a 2 ml amber glass vial in packages of 10 vials. Each ml contains thiothixene hydrochloride equivalent to 2 mg of thiothixene, dextrose 5% w/v, benzyl alcohol 0.9% w/v, and propyl gallate 0.02% w/v.



Navane (thiothixene hydrochloride) Intramuscular For Injection is available in amber glass vials in packages of 10 vials. When reconstituted with 2.2 ml of Sterile Water for Injection, each ml contains thiothixene hydrochloride equivalent to 5 mg of thiothixene, and 59.6 mg of mannitol. The reconstituted solution of Navane Intramuscular For Injection may be stored for 48 hours at room temperature before discarding.

SURVEY OF PSYCHIATRY

This *new* 16-hour program offers a fresh, comprehensive overview of psychiatric theory, practice, and research. Authored by a distinguished faculty, specialists in their field, SURVEY OF PSYCHIATRY presents *completely new,* up-to-date information for the practicing physician who wants to keep abreast of the current state of the art, and may assist for certifying exams (such as the American Board of Psychiatry and Neurology).

Course Director:
Shervert H. Frazier, MD.
Psychiatrist-in-Chief
McLean Hospital Professor of Psychiatry
Harvard Medical School

SURVEY OF PSYCHIATRY has been designed to meet the needs of the busy physician.

- Versatile programs — ideal for home study, teaching, seminars, group study, and refresher courses
- Maximum educational and review benefits in easy-to-use format
- Convenient, flexible — no time spent away from practice

Course Components:

- Audiocassettes — 14 live lectures on 14 audiocassettes
- Course Syllabus (94 pages) — fully illustrated with tables, charts and slide reproductions, plus a concise bibliography for further study
- Test Section — questions and computerized test sheet with self-addressed mailing envelope for registrants desiring Continuing Medical Education Category I credits

Credit Statement:
As an organization accredited by the Liaison Committee on Continuing Medical Education (LCCME) to provide continuing medical education, the American Psychiatric Association certifies that this continuing medical education offering meets the criteria for up to 16 hours of LCCME Category I CME credit, provided it is used and completed as designed.

Order Form

SURVEY OF PSYCHIATRY

Continuing Medical Education Home Study Course
Approved by the APA for 16 Category I credits

Fee: U.S.: $100.00. Foreign: $150.00. U.S. dollars only

A PSYCHIATRIC GLOSSARY

Fifth Edition

Order your copy of the fifth edition of A PSYCHIATRIC GLOSSARY now!

The Glossary has been revised and updated by a Subcommittee of APA's Joint Commission on Public Afairs. It contains current terminology in psychiatry and incorporates the revised nomenclature of DSM III.

A useful, easy-to-use source of information for

—physicians and lawyers

—social workers, psychologists, and nurses

—writers and editors

—teachers and students

Numerous new entries, a series of tables, and a list of abbreviations used in the mental health field are included. Why not order one or more copies of A PSYCHIATRIC GLOSSARY now??

Please send me _____ copies of a PSYCHIATRIC GLOSSARY, 5th edition, paperback. Order number 142.
$5.95 each, 10-24 copies, $5.35 each; 25-99, $5.00 each; 100 or more, $4.75 each

Brief Summary of Prescribing Information

Indications and Usage: Symptomatic relief of anxiety, tension, agitation, irritability and insomnia associated with anxiety neuroses and transient situational disturbances; anxiety associated with depressive symptoms and as a treatment of symptoms of anxiety if such symptoms are a significant feature of functional or organic disorders, particularly gastrointestinal or cardiovascular.

Effectiveness in long-term use, i.e., more than 4 months, has not been assessed by systematic clinical studies. Reassess periodically usefulness of the drug for the individual patient.

Contraindications: Known sensitivity to benzodiazepines or acute narrow-angle glaucoma.

Warnings: Not recommended in primary depressive disorders or psychoses. As with all CNS-acting drugs, warn patients on lorazepam not to operate machinery or motor vehicles, and of diminished tolerance for alcohol and other CNS depressants.

Physical and Psychological Dependence: Withdrawal symptoms like those noted with barbiturates and alcohol have occurred following abrupt discontinuance of benzodiazepines (including convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Addiction-prone individuals, e.g. drug addicts and alcoholics, should be under careful surveillance when on benzodiazepines because of their predisposition to habituation and dependence. Withdrawal symptoms have also been reported following abrupt discontinuance of benzodiazepines taken continuously at therapeutic levels for several months.

Precautions: In depression accompanying anxiety, consider possibility for suicide.

For elderly or debilitated patients, initial daily dosage should not exceed 2mg to avoid oversedation.

Terminate dosage gradually since abrupt withdrawal of any antianxiety agent may result in symptoms like those being treated: anxiety, agitation, irritability, tension, insomnia and occasional convulsions.

Observe usual precautions with impaired renal or hepatic function.

Where gastrointestinal or cardiovascular disorders coexist with anxiety, note that lorazepam has not been shown of significant benefit in treating gastrointestinal or cardiovascular component.

Esophageal dilation occurred in rats treated with lorazepam for more than 1 year at 6mg/kg/day. No effect dose was 1.25mg/kg/day (approximately 6 times the maximum human therapeutic dose of 10mg/day). Effect was reversible only when treatment was withdrawn within 2 months of first observation. Clinical significance is unknown; but use of lorazepam for prolonged periods and in geriatric patients requires caution and frequent monitoring for symptoms of upper G.I. disease.

Safety and effectiveness in children under 12 years have not been established.

ESSENTIAL LABORATORY TESTS: Some patients have developed leukopenia; some have had elevations of LDH. As with other benzodiazepines, periodic blood counts and liver function tests are recommended during long-term therapy.

CLINICALLY SIGNIFICANT DRUG INTERACTIONS: Benzodiazepines produce CNS depressant effects when administered with such medications as barbiturates or alcohol.

CARCINOGENESIS AND MUTAGENESIS: No evidence of carcinogenic potential emerged in rats during an 18-month study. No studies regarding mutagenesis have been performed.

PREGNANCY: Reproductive studies were performed in mice, rats, and 2 strains of rabbits. Occasional anomalies (reduction of tarsals, tibia, metatarsals, malrotated limbs, gastroschisis, malformed skull and microphthalmia) were seen in drug-treated rabbits without relationship to dosage. Although all these anomalies were not present in the concurrent control group, they have been reported to occur randomly in historical controls. At 40mg/kg and higher, there was evidence of fetal resorption and increased fetal loss in rabbits which was not seen at lower doses. Clinical significance of these findings is not known. However, increased risk of congenital malformations associated with use of minor tranquilizers (chlordiazepoxide, diazepam and meprobamate) during first trimester of pregnancy has been suggested in several studies. Because use of these drugs is rarely a matter of urgency, use of lorazepam during this period should almost always be avoided. Possibility that a woman of child-bearing potential may be pregnant at institution of therapy should be considered. Advise patients if they become pregnant to communicate with their physician about desirability of discontinuing the drug.

In humans, blood levels from umbilical cord blood indicate placental transfer of lorazepam and its glucuronide.

NURSING MOTHERS: It is not known if oral lorazepam is excreted in human milk like other benzodiazepines. As a general rule, nursing should not be undertaken while on a drug since many drugs are excreted in milk.

Adverse Reactions, if they occur, are usually observed at beginning of therapy and generally disappear on continued medication or on decreasing dose. In a sample of about 3,500 anxious patients, most frequent adverse reaction is sedation (15.9%), followed by dizziness (6.9%), weakness (4.2%) and unsteadiness (3.4%). Less frequent are disorientation, depression, nausea, change in appetite, headache, sleep disturbance, agitation, dermatological symptoms, eye function disturbance, various gastrointestinal symptoms and autonomic manifestations. Incidence of sedation and unsteadiness increased with age. Small decreases in blood pressure have been noted but are not clinically significant, probably being related to relief of anxiety.

Overdosage: In management of overdosage with any drug, bear in mind that multiple agents may have been taken. Manifestations of overdosage include somnolence, confusion and coma. Induce vomiting and/or undertake gastric lavage followed by general supportive care, monitoring of vital signs and close observation. Hypotension, though unlikely, usually may be controlled with Levarterenol Bitartrate Injection U.S.P. Usefulness of dialysis has not been determined.

Ativan® IV for Anxiety (lorazepam)

Dosage: **Individualize for maximum beneficial effects. Increase dose gradually when needed, giving higher evening dose before increasing daytime doses. Anxiety, usually 2-3mg/day given b.i.d. or t.i.d.; dosage may vary from 1 to 10mg/day in divided doses. For elderly or debilitated, initially 1-2mg/day; insomnia due to anxiety or transient situational stress, 2-4mg h.s.**

How Supplied: **0.5, 1.0 and 2.0mg tablets.**

Wyeth Laboratories

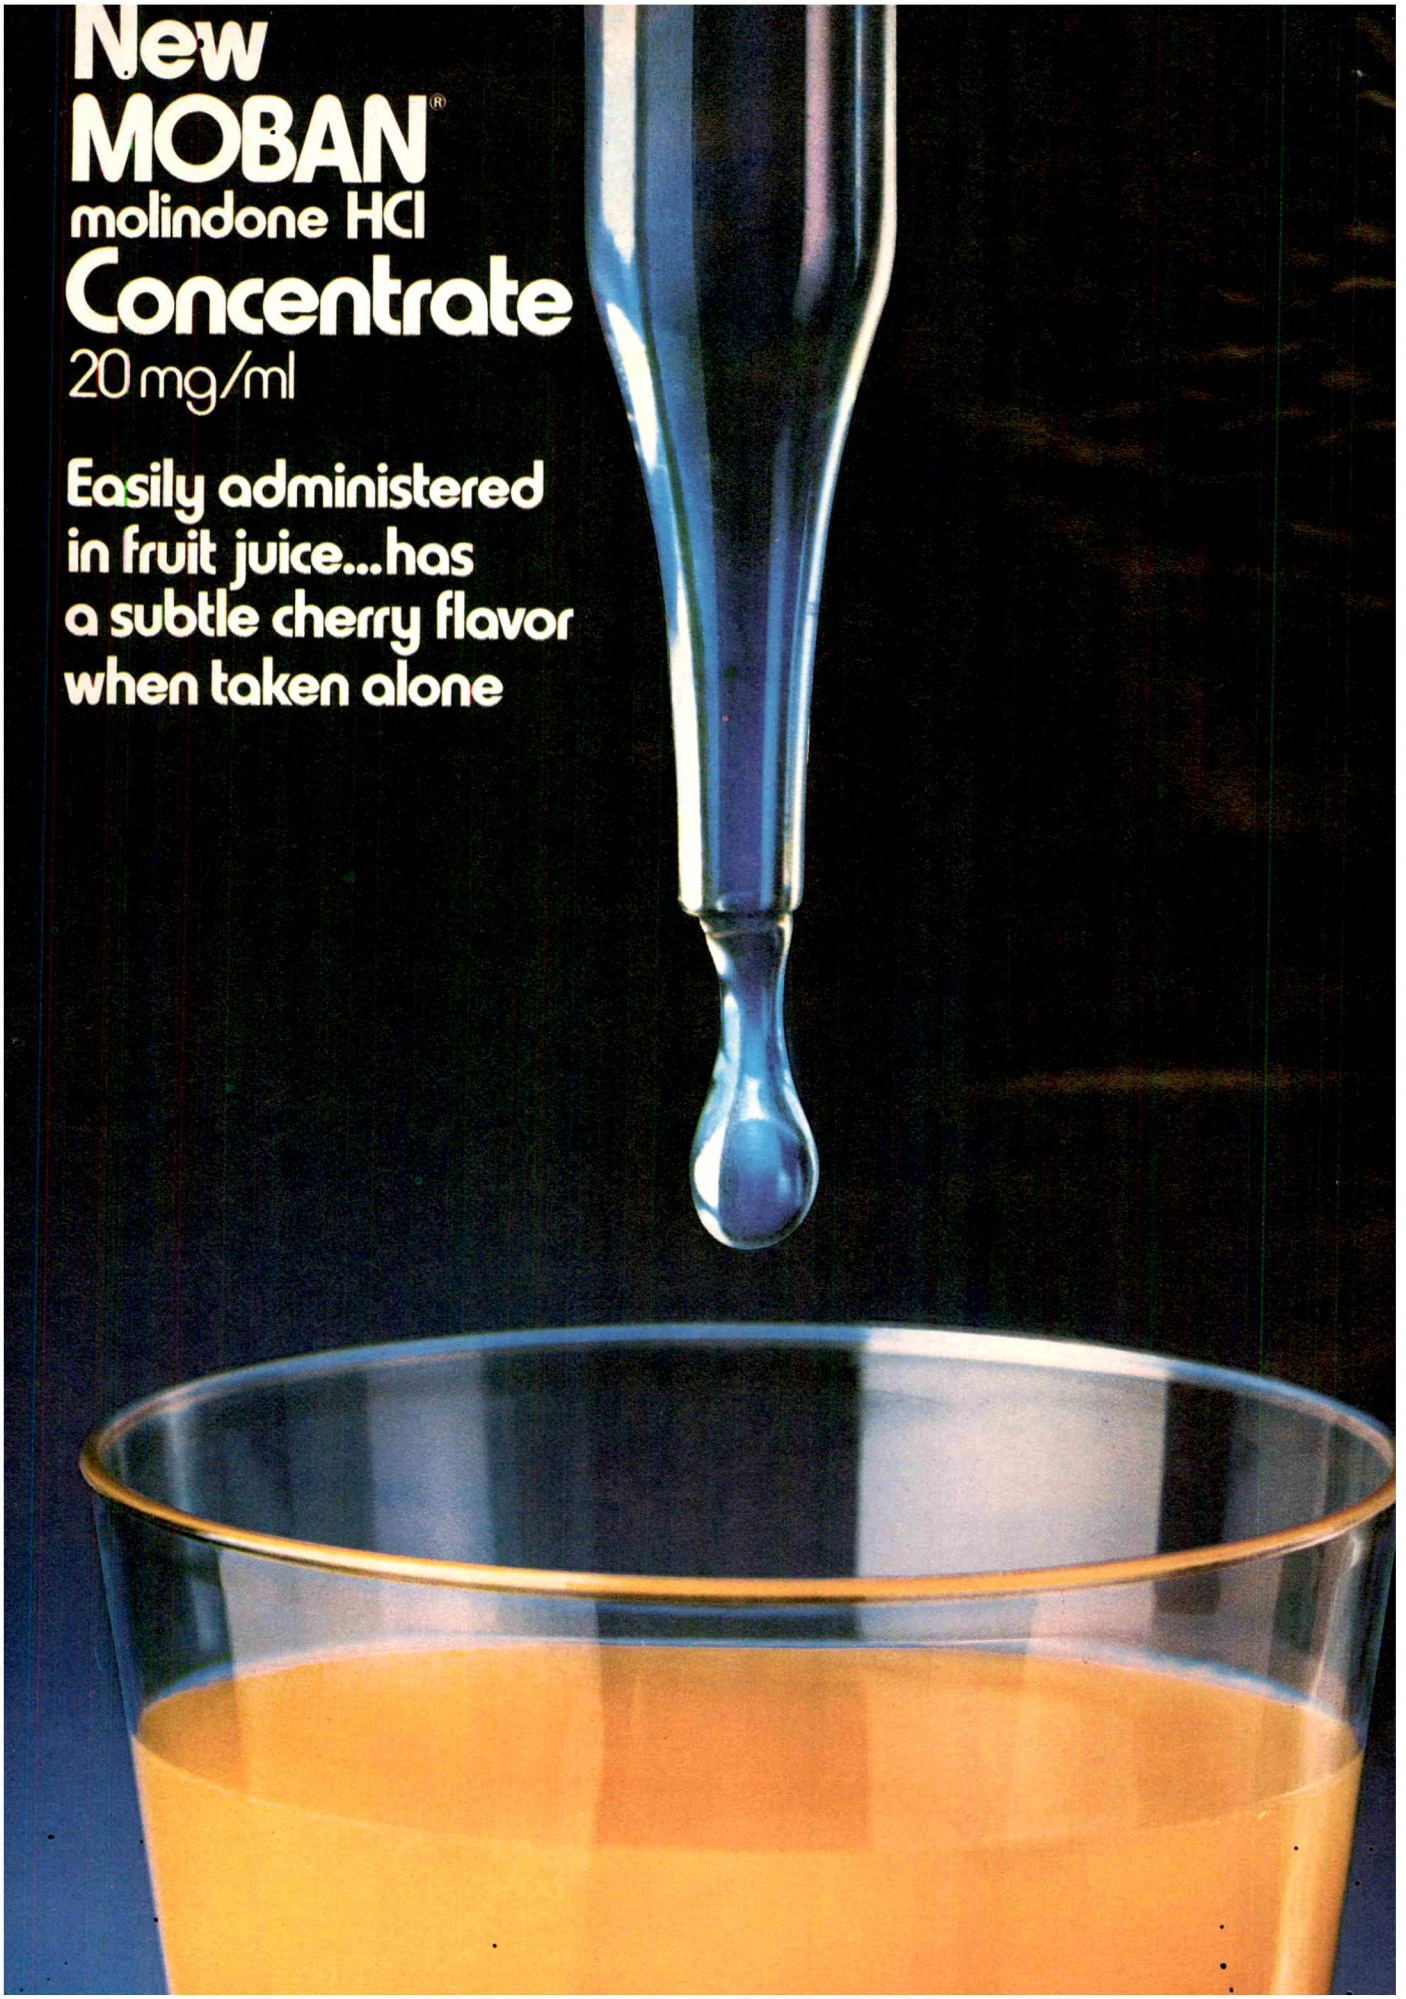
A mixed syndrome. When drug intervention is indicated in patients whose anxiety is accompanied by depressive symptoms, the choice, essentially, is among three basic strategies: (1) an antidepressant; (2) a tranquilizer; (3) a combination of (1) and (2).

With respect to strategy (2), you should know that Ativan (lorazepam) has been shown to be statistically and clinically significantly effective in alleviating the anxiety component of this mixed syndrome, in common protocol controlled studies of 653 patients (337 on Ativan).



Since Ativan was also found to be compatible with tricyclics, if you opt for strategy (3), your patient has the benefit of rapid anxiolytic action, absence of long-acting metabolites and rapid clearance when you decide to discontinue Ativan. All benzodiazepines, however, including Ativan, produce added CNS depressant effects when administered with alcohol and other CNS depressants.

In either case, Ativan offers you the convenience of a b.i.d. schedule and a flexibility not possible with any fixed combination.

See important information on preceding page.

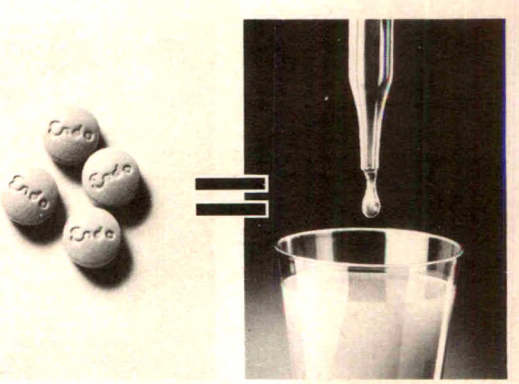
associated with depressive symptoms

New
MOBAN®
molindone HCl
Concentrate
20 mg/ml
Easily administered
in fruit juice...has
a subtle cherry flavor
when taken alone



An effective antipsychotic agent with a favorable benefit/risk profile

NO incidence	excessive weight gain hepatotoxic changes ophthalmological changes persistent tardive dyskinesia skin pigmentation thyroid function changes tolerance development
LOW incidence	adverse drug interactions hematological changes hypotension nonpersistent symptoms of tardive dyskinesia sedation
MODERATE incidence	extrapyramidal reactions

This table compiled from clinical and field reports, according to the best available information.

For the schizophrenic patient

New MOBAN® molindone HCl Concentrate 20 mg/ml

four 25 mg tablets = 5 milliliters (100 mg)

Concentrated for maximum convenience of higher dosages...easy titration... enhanced compliance

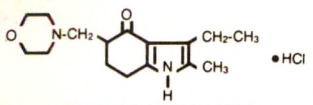
Initial dosage with MOBAN®

- usual starting dose is 50-75 mg/day
- may be increased to 100 mg/day in three to four days
- may be adjusted up or down according to response
- some patients with severe symptomatology may require an increase to 225 mg/day
- elderly and debilitated patients should be started on lower dosage

Please see next page for prescribing information.

Endo Laboratories DU·PONT

An effective antipsychotic agent



MOBAN®
molindone HCl

New dosage form... Concentrate 20 mg/ml

continuing...Tablets 5 mg, 10 mg, 25 mg

DESCRIPTION MOBAN (molindone hydrochloride) is a dihydroindolone compound which is not structurally related to the phenothiazines, the butyrophenones or the thioxanthenes.

MOBAN is 3-ethyl-6, 7-dihydro-2-methyl-5-(morpholinomethyl) indol-4 (5H)-one hydrochloride. It is a white crystalline powder, freely soluble in water and alcohol and has a molecular weight of 312.67.

MOLINDONE HYDROCHLORIDE

ACTIONS MOBAN (molindone hydrochloride) has a pharmacological profile in laboratory animals which predominantly resembles that of major tranquilizers causing reduction of spontaneous locomotion and aggressiveness, suppression of a conditioned response and antagonism of the bizarre stereotyped behavior and hyperactivity induced by amphetamines. In addition, MOBAN antagonizes the depression caused by the tranquilizing agent tetrabenazine.

In human clinical studies tranquilization is achieved in the absence of muscle relaxing or incoordinating effects. Based on EEG studies, MOBAN exerts its effect on the ascending reticular activating system.

Human metabolic studies show MOBAN (molindone hydrochloride) to be rapidly absorbed and metabolized when given orally. Unmetabolized drug reached a peak blood level at 1.5 hours. Pharmacological effect from a single oral dose persists for 24-36 hours. There are 36 recognized metabolites with less than 2-3% unmetabolized MOBAN being excreted in urine and feces.

INDICATIONS MOBAN (molindone hydrochloride) is indicated in the management of the manifestations of schizophrenia.

CONTRAINDICATIONS MOBAN (molindone hydrochloride) is contraindicated in severe central nervous system depression (alcohol, barbiturates, narcotics, etc.) or comatose states, and in patients with known hypersensitivity to the drug.

WARNINGS Usage in Pregnancy: Studies in pregnant patients have not been carried out. Reproduction studies have been performed in the following animals:

Pregnant Rats oral dose— 20 mg/kg/day—10 days
no adverse effect
40 mg/kg/day—10 days
no adverse effect

Pregnant Mice oral dose— 20 mg/kg/day—10 days
slight increase resorptions
40 mg/kg/day—10 days
slight increase resorptions

Pregnant Rabbits oral dose— 5 mg/kg/day—12 days
no adverse effect
10 mg/kg/day—12 days
no adverse effect
20 mg/kg/day—12 days
no adverse effect

Animal reproductive studies have not demonstrated a teratogenic potential. The anticipated benefits must be weighed against the unknown risks to the fetus if used in pregnant patients.

Nursing Mothers: Data are not available on the content of MOBAN (molindone hydrochloride) in the milk of nursing mothers.

Usage in Children: Use of MOBAN (molindone hydrochloride) in children below the age of twelve years is not recommended because safe and effective conditions for its usage have not been established.

MOBAN has not been shown effective in the management of behavioral complications in patients with mental retardation.

PRECAUTIONS Some patients receiving MOBAN (molindone hydrochloride) may note drowsiness initially and they should be advised against activities requiring mental alertness until their response to the drug has been established.

Increased activity has been noted in patients receiving MOBAN. Caution should be exercised where increased activity may be harmful.

MOBAN does not lower the seizure threshold in experimental animals to the degree noted with more sedating antipsychotic drugs. However, in humans convulsive seizures have been reported in a few instances.

EDO 854M580

The physician should be aware that this tablet preparation contains calcium sulfate as an excipient and that calcium ions may interfere with the absorption of preparations containing phenytoin sodium and tetracyclines.

MOBAN (molindone hydrochloride) has an antiemetic effect in animals. A similar effect may occur in humans and may obscure signs of intestinal obstruction or brain tumor.

ADVERSE REACTIONS—CNS EFFECTS The most frequently occurring effect is initial drowsiness that generally subsides with continued usage of the drug or lowering of the dose.

Noted less frequently were depression, hyperactivity and euphoria.

Neurological—Extrapyramidal Reactions Extrapyramidal reactions noted below may occur in susceptible individuals and are usually reversible with appropriate management.

Akathisia Motor restlessness may occur early.

Parkinson Syndrome Akinesia, characterized by rigidity, immobility and reduction of voluntary movements and tremor, have been observed. Occurrence is less frequent than akathisia.

Dystonic Syndrome Prolonged abnormal contractions of muscle groups occur infrequently. These symptoms may be managed by the addition of a synthetic antiparkinson agent (other than L-dopa), small doses of sedative drugs, and/or reduction in dosage.

Autonomic Nervous System Occasionally blurring of vision, tachycardia, nausea, dry mouth and salivation have been reported. Urinary retention and constipation may occur particularly if anticholinergic drugs are used to treat extrapyramidal symptoms.

Hematological There have been rare reports of leucopenia and leucocytosis. If such reactions occur, treatment with MOBAN may continue if clinical symptoms are absent. Alterations of blood glucose, liver function tests, B.U.N., and red blood cells have not been considered clinically significant.

Metabolic and Endocrine Effects Alteration of thyroid function has not been significant. Amenorrhea has been reported infrequently. Resumption of menses in previously amenorrheic women has been reported. Initially heavy menses may occur. Galactorrhea and gynecomastia have been reported infrequently. Increase in libido has been noted in some patients. Impotence has not been reported. Although both weight gain and weight loss have been in the direction of normal or ideal weight, excessive weight gain has not occurred with MOBAN.

Cardiovascular Rare, transient, non-specific T wave changes have been reported on E.K.G. Association with a clinical syndrome has not been established. Rarely has significant hypotension been reported.

Ophthalmological Lens opacities and pigmentary retinopathy have not been reported where patients have received MOBAN (molindone hydrochloride). In some patients, phenothiazine induced lenticular opacities have resolved following discontinuation of the phenothiazine while continuing therapy with MOBAN.

Skin Early, non-specific skin rash, probably of allergic origin, has occasionally been reported. Skin pigmentation has not been seen with MOBAN usage alone.

MOBAN (molindone hydrochloride) has certain pharmacological similarities to other antipsychotic agents. Because adverse reactions are often extensions of the pharmacological activity of a drug, all of the known pharmacological effects associated with other antipsychotic drugs should be kept in mind when MOBAN is used. Upon abrupt withdrawal after prolonged high dosage an abstinence syndrome has not been noted.

Tardive Dyskinesia Although rarely reported with MOBAN (molindone hydrochloride) symptoms were reversible upon discontinuation of therapy.

Tardive dyskinesia associated with other agents has appeared in some patients on long-term therapy and has also appeared after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). There may be involuntary movements of extremities.

There is no known effective treatment of tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine vermicular movements of the tongue may be an early sign of the syndrome and if the medication is stopped at that time the syndrome may not develop.

DOSAGE AND ADMINISTRATION Initial and maintenance doses of MOBAN (molindone hydrochloride) should be individualized.

Initial Dosage Schedule The usual starting dosage is 50-75 mg/day.
- —Increase to 100 mg/day in 3 or 4 days.
- —Based on severity of symptomatology, dosage may be titrated up or down depending on individual patient response.
- —An increase to 225 mg/day may be required in patients with severe symptomatology.

Elderly and debilitated patients should be started on lower dosage.

Maintenance Dosage Schedule
1. Mild—5 mg-15 mg three or four times a day.
2. Moderate—10 mg-25 mg three or four times a day.
3. Severe—225 mg/day may be required.

DRUG INTERACTIONS Potentiation of drugs administered concurrently with MOBAN (molindone hydrochloride) has not been reported. Additionally, animal studies have not shown increased toxicity when MOBAN is given concurrently with representative members of three classes of drugs (i.e., barbiturates, chloral hydrate and antiparkinson drugs).

MANAGEMENT OF OVERDOSAGE Symptomatic, supportive therapy should be the rule.

Gastric lavage is indicated for the reduction of absorption of MOBAN (molindone hydrochloride) which is freely soluble in water.

Since the adsorption of MOBAN (molindone hydrochloride) by activated charcoal has not been determined, the use of this antidote must be considered of theoretical value.

Emesis in a comatose patient is contraindicated. Additionally, while the emetic effect of apomorphine is blocked by MOBAN in animals, this blocking effect has not been determined in humans.

A significant increase in the rate of removal of unmetabolized MOBAN (molindone hydrochloride) from the body by forced diuresis, peritoneal or renal dialysis would not be expected. (Only 2% of a single ingested dose of MOBAN is excreted unmetabolized in the urine.)

However, poor response of the patient may justify use of these procedures. While the use of laxatives or enemas might be based on general principles, the amount of unmetabolized MOBAN in feces is less than 1%. Extrapyramidal symptoms have responded to the use of diphenhydramine (Benadryl*) and the synthetic anticholinergic antiparkinson agents, (i.e., Artane*, Cogentin*, Akineton*).

HOW SUPPLIED As tablets in bottles with potencies and colors as follows:

100's and 1000's:
5 mg orange
10 mg lavender
25 mg light green

As a concentrate containing 20 mg molindone hydrochloride per ml in 4 oz. (120ml) bottles.

*Benadryl—Trademark, Parke Davis and Co.
*Artane—Trademark, Lederle Laboratories
*Cogentin—Trademark, Merck Sharp & Dohme
*Akineton—Trademark, Knoll Pharmaceutical Co.

DSM-III

The American Psychiatric Association's First Major Revision of the Psychiatric Nomenclature in 12 Years

This long awaited revision of the **Diagnostic and Statistical Manual of Mental Disorders** has taken five years to develop and field test. The result is a 500-page text which is unsurpassed in its completeness, clinical reliability, and description of criteria and codes for psychiatric diagnostic classification. The book incorporates a revision of the diagnostic classifications of DSM-II with an extensive listing of new diagnostic criteria, decision trees for differential diagnosis, a glossary of technical terms, an annotated comparative listing of DSM-II and DSM-III classifications, and an historical review of ICD-9 and ICD-9-CM classifications.

A Compact, Quick-Reference Guide

In making a DSM-III diagnosis, clinicians and researchers may find it convenient to consult the **Quick Reference to the Diagnostic Criteria,** a pocket-sized booklet that contains only the classification, the diagnostic criteria, and a listing of the most important conditions to be considered in a differential diagnosis of each category.

Order Now. Mail coupon to The American Psychiatric Association, Publication Sales, 1700 18th Street, N.W., Washington, D.C. 20009.

Please send me _____ copies of **DSM-III** (hardbound edition), Order #143 @ $25.00.
_____ copies of the **DSM-III** (paperback edition), Order #143-1 @ $20.00.
_____ copies of the **Quick Reference to the Diagnostic Criteria** (paperback), Order #144 @ $10.00
_____ sets (Hardbound **DSM-III** and **Quick Reference to the Diagnostic Criteria**), Order #407 @ $31.00.

Bulk discounts: 10–24 copies, 10% discount per title; 25–99 copies, 15% discount per title; 100 or more copies, 20% discount per title. No bulk discount is available on the Set.

ENCLOSED IS A TOTAL PAYMENT OF $ _____.

(All domestic orders amounting to $35.00 or less must be accompanied by payment. All foreign orders, regardless of dollar amount, must be accompanied by payment. Non-prepaid orders (over $35.00) will be invoiced with shipping/handling charges included.)

Lithobid™

Slow-Release Lithium Carbonate 300 mg.

Before prescribing, see complete prescribing information in Rowell literature. The following is a brief summary.

WARNING
Lithium toxicity is closely related to serum lithium levels, and can occur at doses close to therapeutic levels. Facilities for prompt and accurate serum lithium determinations should be available before initiating therapy.

Indications: Treatment of manic episodes of manic-depressive illness. Maintenance therapy prevents or diminishes the intensity of subsequent episodes in manic-depressive patients with a history of mania.

Warnings: Lithium should generally not be given to patients with significant renal or cardiovascular disease, severe debilitation or dehydration, sodium depletion, or to patients receiving diuretics.

Lithium therapy has been reported in some cases to be associated with morphologic changes in the kidneys.

Caution patient and family to watch for diarrhea, vomiting, tremor, mild ataxia, drowsiness, or muscular weakness as signs of lithium toxicity, and to discontinue therapy and contact a physician should they occur. Patients receiving combined therapy with lithium and an antipsychotic should be monitored closely for early evidence of neurologic toxicity and treatment discontinued promptly if such signs appear. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery).

Lithium should not be used in pregnancy, especially during the first trimester, unless potential benefits outweigh possible hazards.

Not recommended for children under 12.

Precautions: Lithium tolerance is greater during the acute manic phase and decreases when manic symptoms subside.

Lithium therapy may lead to sodium depletion. Normal diet (including salt) and adequate fluid intake (2500-3000 ml) must be maintained, at least during initial stabilization period. Protracted sweating or diarrhea can decrease tolerance; in such cases, administer supplemental fluid and salt.

Each tablet contains 40 mg of sodium chloride, equivalent to 15.7 mg of sodium.

Sweating, diarrhea, and concomitant infection with elevated temperatures may require temporary reduction or cessation of dosage.

Adverse Reactions: Mild to moderate toxic reactions may occur at serum lithium levels from 1.5 to 2.5 mEq/L, and moderate to severe reactions at levels from 2.0 to 2.5 mEq/L. Fine hand tremor, polyuria, and mild thirst may occur during initial therapy and persist. Transient and mild nausea and general discomfort also appear during initial therapy. These effects usually subside with continued treatment or temporary reduction or cessation of dosage. If persistent, discontinue dosage.

Diarrhea, vomiting, drowsiness, muscular weakness, and lack of coordination may be early signs of toxicity and may occur at levels below 2.0 mEq/L. At higher levels, ataxia, giddiness, tinnitus, blurred vision, and a large output of dilute urine may be seen. Serum levels above 3.0 mEq/L may produce a complex clinical picture, involving multiple organs and systems. Serum levels should not exceed 2.0 mEq/L during acute phase.

The following reactions appear to be related to serum lithium levels, including levels within the therapeutic range: Neuromuscular—tremor, muscle hyperirritability (fasciculations, twitching, clonic movements of whole limbs), ataxia, choreo-athetotic movements, hyperactive deep tendon reflex; Central Nervous System—blackout spells, epileptiform seizures, slurred speech, dizziness, vertigo, incontinence of urine or feces, somnolence, psychomotor retardation, restlessness, confusion, stupor, coma; Cardiovascular—cardiac arrhythmia, hypotension, peripheral circulatory collapse; Gastrointestinal—anorexia, nausea, vomiting, diarrhea; Genitourinary—albuminuria, oliguria, polyuria, glycosuria; Dermatologic—drying and thinning of hair, alopecia, anesthesia of skin, chronic folliculitis, exacerbation of psoriasis, xerosis cutis; Autonomic—blurred vision, dry mouth; Thyroid Abnormalities—euthyroid goiter and/or hypothyroidism (including myxedema) with lower T_3 and T_4. I^{131} uptake may be elevated; EEG Changes—diffuse slowing, widening of the frequency spectrum, potentiation and disorganization of background rhythm; EKG Changes—reversible flattening, isoelectricity or inversion of T-waves; Miscellaneous—fatigue, lethargy, transient scotomata, dehydration, weight loss, tendency to sleep.

Reactions unrelated to dosage include: transient EEG and EKG changes, leukocytosis, headache, diffuse nontoxic goiter with or without hypothyroidism, transient hyperglycemia, generalized pruritus with or without rash, cutaneous ulcers, albuminuria, worsening of organic brain syndromes, excessive weight gain, edematous swelling of ankles or wrists, thirst or polyuria, sometimes resembling diabetes insipidus, and metallic taste. A single case of a syndrome resembling Raynaud's has been reported.

Dosage and Administration: *Acute Mania*—900 mg b.i.d. or 600 mg t.i.d. (1800 mg per day) usually will provide serum lithium levels ranging between 1.0 and 1.5 mEq/L. Serum levels should be determined twice per week until serum level and clinical condition have been stabilized.

Long-Term Control—900 mg to 1200 mg per day in two or three divided doses usually will maintain serum lithium levels at 0.6 to 1.2 mEq/L. Serum lithium levels should be monitored at least every two months.

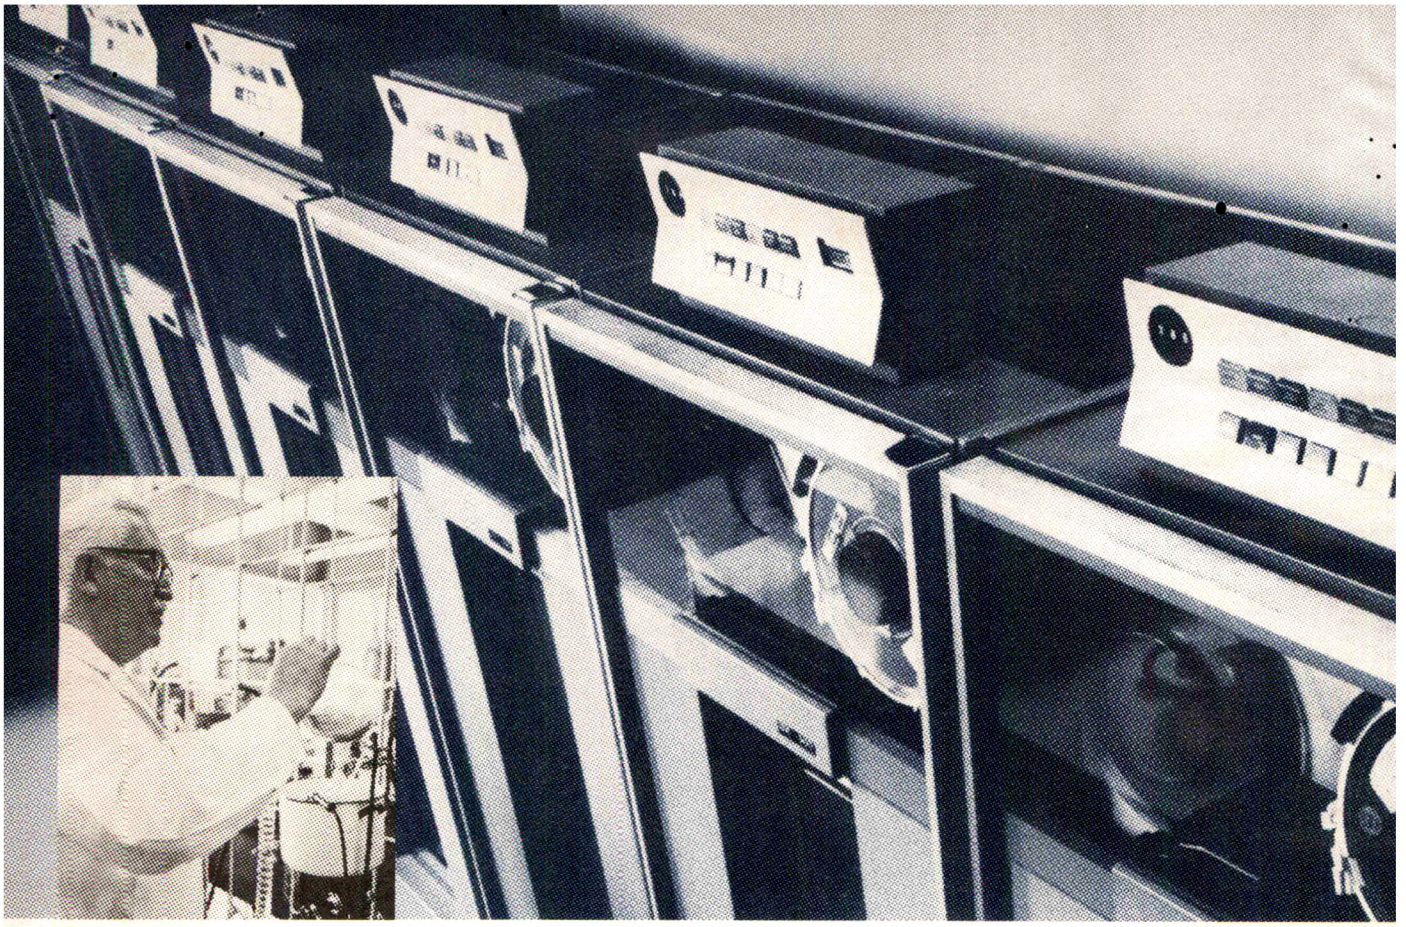
How Supplied: 300 mg peach-colored tablets, imprinted "ROWELL 7514" in red, are supplied in bottles of 100 and 1000.

ROWELL LABORATORIES, INC.
BAUDETTE, MINN. 56623

Do lithium dosage schedules keep your patients going around in circles?

Slow-Release Lithobid enables twice-a-day dosing as a practical route to better patient compliance. Patients on conventional lithium dosage forms can be converted to new Lithobid at the same daily dose, divided b.i.d. All patients on long-term lithium maintenance therapy will appreciate the convenience of this reduced dosage frequency.

Conventional tablets or capsules cause serum lithium spikes. New Lithobid blunts these peaks and keeps post-absorption serum levels within bounds.



Lithobid™
Slow-Release Lithium Carbonate 300 mg.

Now you can convert your lithium patients to this convenient, new b.i.d. dosage.

1E May, 1979

proven antianxiety

Highly specific calming action virtually free of unwanted side effects: this was the remarkable clinical promise of Librium (chlordiazepoxide HCl). And today this promise continues to be fulfilled in a wide variety of patients you see every day.

ROCHE

The published record on Librium is enormous. So large, in fact, it had to be put into a computer data bank and retrieval system. It's a record that shows Librium is highly effective in relieving anxiety; that Librium is seldom associated with serious side effects; that Librium rarely interferes with mental acuity at proper doses; that Librium is used concomitantly with primary medications. However, as with all CNS agents, patients should be warned against hazardous activities requiring complete alertness, and about possible combined effects with alcohol.

performance

Librium®

chlordiazepoxide HCl/Roche

5mg, 10mg, 25mg capsules

synonymous with relief of anxiety

- ☐ An unsurpassed safety record
- ☐ Minimal effect on mental acuity, in proper dosage
- ☐ Predictable patient response
- ☐ Is used concomitantly with primary medications, such as anticholinergics and cardiovascular drugs

Please see next page for summary of product information.

Librium® 5mg, 10mg, 25mg capsules
chlordiazepoxide HCl/Roche

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Relief of anxiety and tension occurring alone or accompanying various disease states. Efficacy beyond four months not established by systematic clinical studies. Periodic reassessment of therapy recommended.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Warn patients that mental and/or physical abilities required for tasks such as driving or operating machinery may be impaired, as may be mental alertness in children, and that concomitant use with alcohol or CNS depressants may have an additive effect. Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported.

***Usage in Pregnancy:* Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral–Adults:* Mild and moderate anxiety and tension, 5 or 10 mg *t.i.d.* or *q.i.d.*; severe states, 20 or 25 mg *t.i.d.* or *q.i.d. Geriatric patients:* 5 mg *b.i.d.* to *q.i.d.* (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) *Capsules*, 5 mg, 10 mg and 25 mg—bottles of 100 and 500; Tel-E-Dose® packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10. Libritabs® (chlordiazepoxide) *Tablets*, 5 mg, 10 mg and 25 mg—bottles of 100 and 500. With respect to clinical activity, capsules and tablets are indistinguishable.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

It should be noted that efficacy, indications and untoward effects have varied with the different phenothiazines. It has been reported that old age lowers the tolerance for phenothiazines; the most common neurologic side effects are parkinsonism and akathisia, and the risk of agranulocytosis and leukopenia increases. The following reactions have occurred with phenothiazines and should be considered whenever one of these drugs is used. *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Dosage: Dosage must be individualized according to the degree of mental and emotional disturbance, and the smallest effective dosage should be determined for each patient.

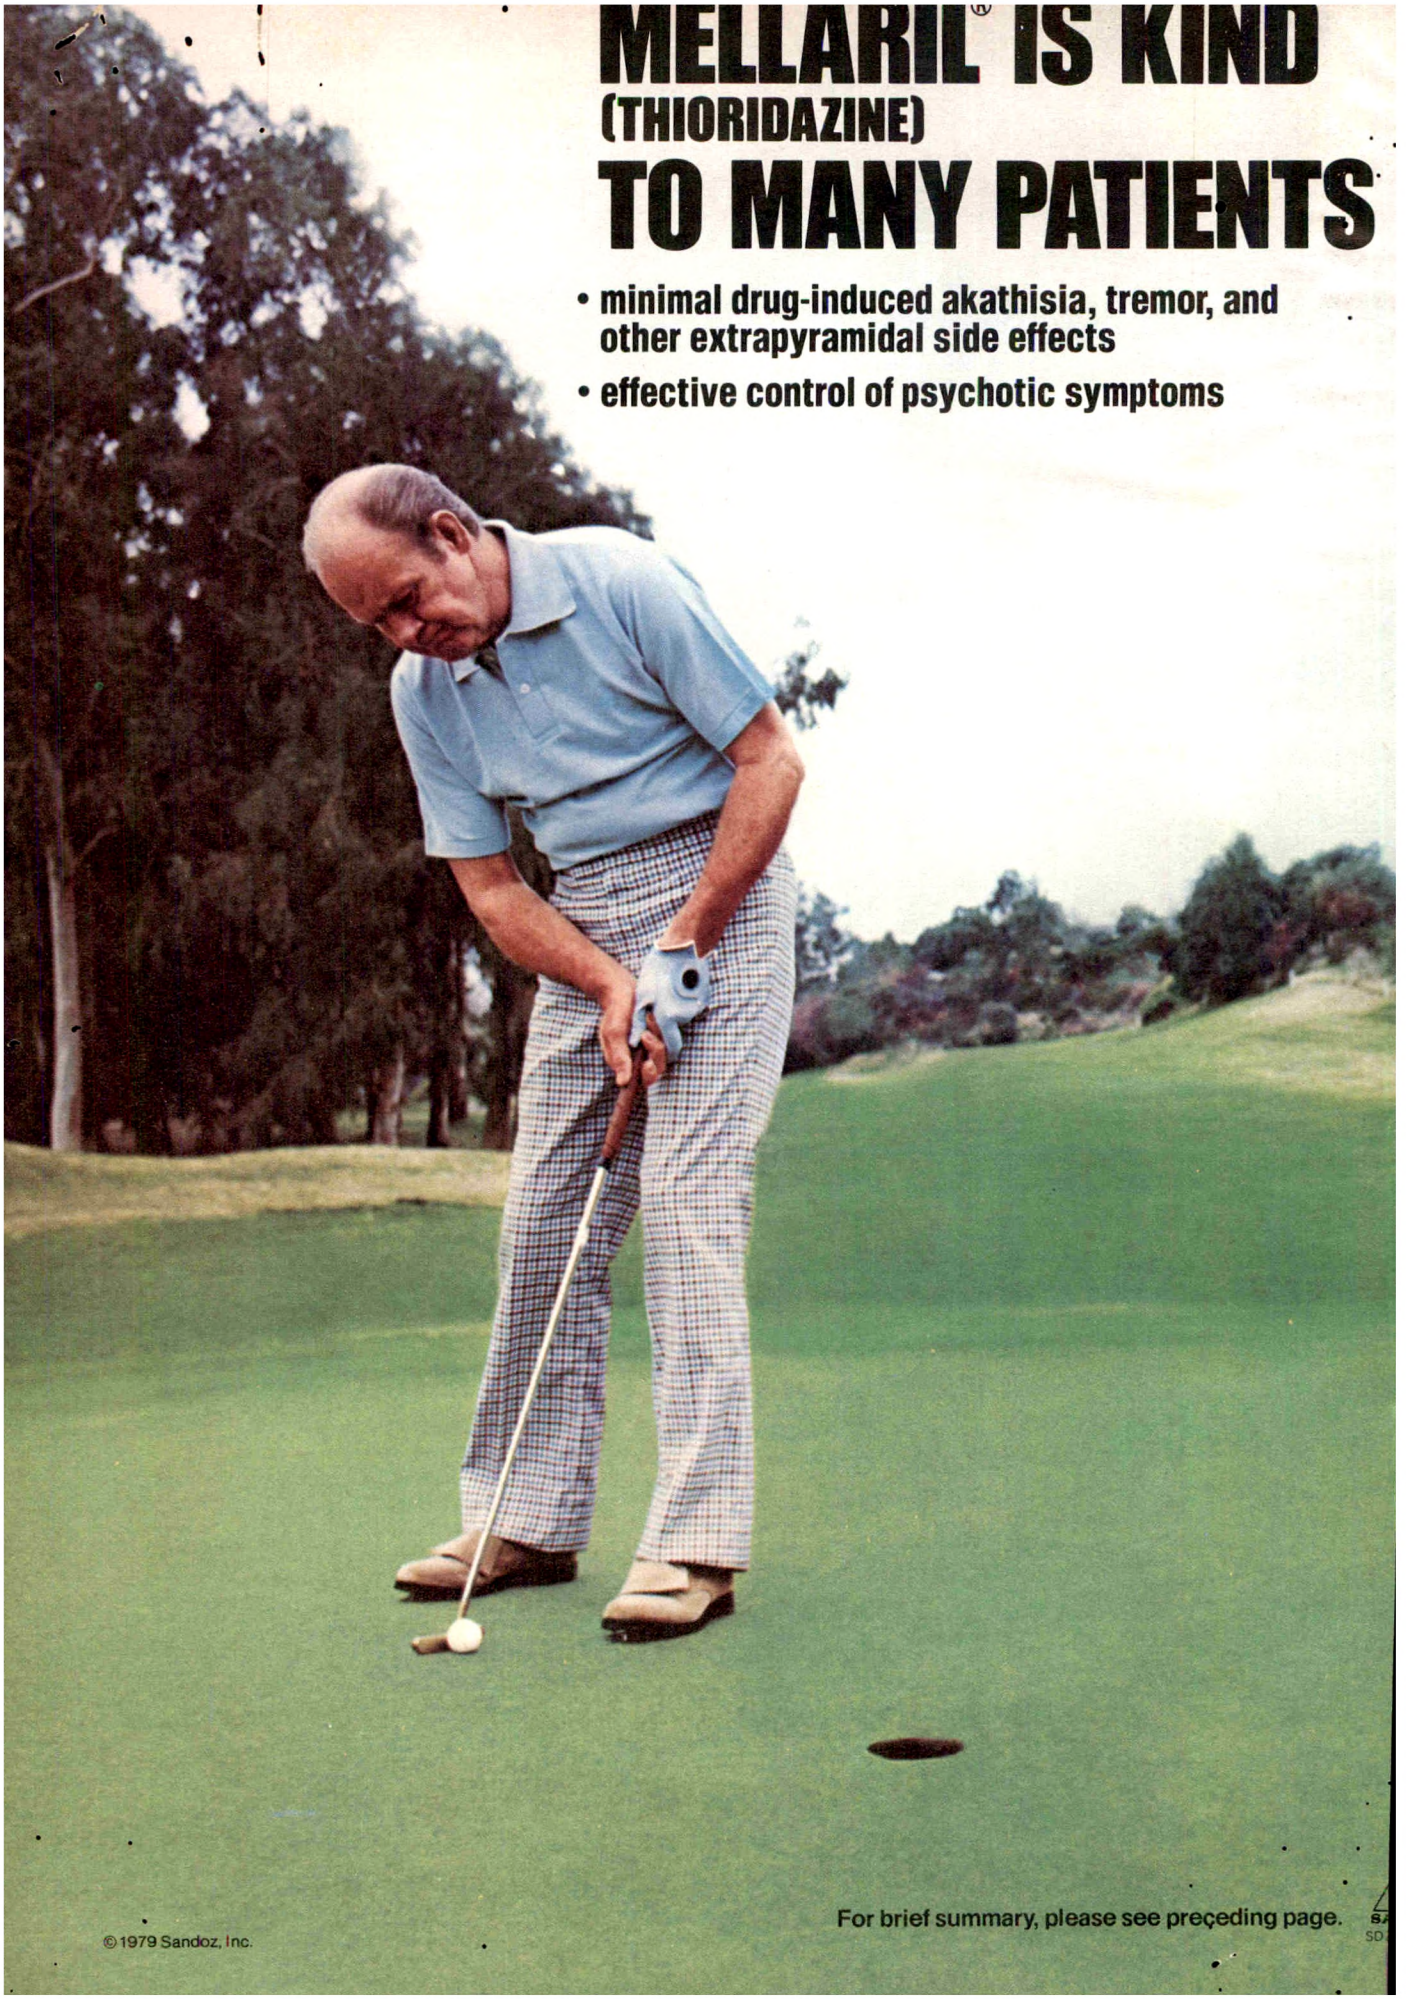
SANDOZ

SDZ 9-406R1

MELLARIL® IS KIND (THIORIDAZINE) TO MANY PATIENTS

- **minimal drug-induced akathisia, tremor, and other extrapyramidal side effects**
- **effective control of psychotic symptoms**



Mellaril® (thioridazine) is kind *two* ways to the patient with psychotic symptoms. It has an impressive record of relieving agitation, excitement, and hallucinations, while successfully helping the patient live and perform in the community. And, unlike other major tranquilizers, Mellaril (thioridazine) causes minimal akathisia or other extrapyramidal symptoms. Mellaril (thioridazine) is contraindicated in patients with hypertensive or hypotensive heart disease of extreme degree.

Effectiveness plus infrequent side effects—that's the kind of kindness the physician likes to see in a major tranquilizer!

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, USP

MELLARIL-S™ (thioridazine) SUSPENSION, per 5 ml (teaspoon): thioridazine base equivalent to 100 mg thioridazine HCl, USP

MELLARIL® IS KIND (THIORIDAZINE) TO MANY PATIENTS

- minimal drug-induced akathisia, tremor, and other extrapyramidal side effects
- effective control of psychotic symptoms

THE AMERICAN JOURNAL OF PSYCHIATRY

Overview: Model Programs for Chronic Mental Patients

BY LEONA L. BACHRACH, PH.D.

Model programs for chronic mental patients may be viewed from four perspectives: evaluation of individual programs, commonalities in successful programs, generalizability and reproducibility of specific programs, and relevance of model programs to problems of service delivery in mental health systems. Although successful model programs share certain common structural elements, such programs cannot be readily reproduced or generalized. Having limited value for the problems of service delivery in mental health systems, model programs are best seen as experimental efforts, not as solutions. Strategies for translating model-derived knowledge into systems-related action are needed.

In the past two decades a sizable number of "model programs" have been developed to care for chronic mental patients in nontraditional and noninstitutional settings. Considered together, these programs are quite extraordinary. It is unlikely that 20 years ago many caregivers and service planners could have foreseen that so much creativity and innovativeness could be applied to the development of special programs for this patient population. As efforts to reverse the effects of institutionalism continue, the success of these programs provides hope for future service planning.

Simultaneously, however, the literature is replete with descriptions of failures in the care of chronic mental patients. Professional and popular sources alike report that the chronically mentally ill, in general, are not being adequately and humanely served by existing programs and that these patients are regularly overlooked by the mental health service system. When it comes to caring for chronic mental patients, service systems are typically reported to be fragmented and unresponsive, and the most seriously ill are more often than not described as "falling through the cracks."

How can these reports of successful model programs and glaring service system deficits be reconciled? What, precisely, is the relationship between demonstration efforts and the realities of mental health service systems? In this paper I will provide a conceptual framework for evaluating model programs for chronic mental patients and examine their contributions, their limitations, and their relationship to mental health service systems.

In this context the term "model program" is defined as any planned demonstration effort that tests the application of distinctive, often innovative, programmatic strategies to the care of chronic mental patients. Model programs are generally, although not necessarily, small in size, and their participants are usually selected in accord with the program's experimental aims. Often, although again not necessarily, funding of these programs is provided by external agencies for the specific purpose of testing special procedures or treatments.

Model programs for chronic mental patients are not limited to any particular setting. They may be administered under public or private auspices and have been described as occurring in such diverse places as general hospitals, community mental health centers, community action agencies, state mental hospitals, and even as part of a private psychiatric group practice (1-3). One model program reportedly operates on the streets of New York City. Funded by the state's office of mental health, that program uses a mobile van to seek out "shopping bag" people and others in need and to deliver them to treatment settings (4). Not to

be confused in any way with the "medical" versus "nonmedical" treatment model controversy, model programs for chronic mental patients encompass a wide variety of treatment modalities, some fairly traditional and others decidedly innovative in nature.

Despite enthusiastic reports that many model programs are meeting the diverse needs of chronic mental patients effectively and compassionately, I have suggested elsewhere (5) that there are limits to the generalizability and reproducibility of these programs—that, in fact, they have often been used inappropriately to provide "answers" to questions concerning problems currently experienced by mental health service systems. Actually, model programs may be viewed from a variety of perspectives. In this paper I will discuss four different ways of looking at model programs for the care of chronic mental patients. The conceptual approach used is a layered one in which model programs are assessed through a series of questions representing different levels of abstraction, ranging from the most specific to the most general.

The first level of abstraction is evaluation and focuses on the question of how well any individual model program works. This is the lowest level of abstraction in that it looks at each program separately and makes no attempt at generalization. A second and higher level of abstraction is comparative and inquires as to whether there are principles common to model programs that may be extracted from them. Moving up the ladder of abstraction, a third approach assesses the generalizability of model programs and inquires into their reproducibility in settings other than their original locations. The fourth and highest level of abstraction is, like the first, evaluative, but with a major difference. The question here, instead of looking inward to the workings of individual programs, looks outward and asks, So what? This dimension of relevance focuses on the broader implications of model programs for the delivery of services to the total population of people who are chronically mentally disabled.

LEVEL I: EVALUATION OF INDIVIDUAL PROGRAMS

Every model program for chronic mental patients may be evaluated as an individual entity. Although evaluation of this kind is very important, it will be discussed only briefly because much has already been written on the need for adequate program evaluation (6–8).

Typically, evaluation of individual programs measures programmatic relevance and outcomes according to predefined criteria and is performed in-house or under contract. Evaluation of models, like evaluation of their nonmodel counterparts, may proceed in a variety of ways, depending on what information is being sought. It might, for example, depart from externally determined criteria for the effectiveness of community-based programs such as those proposed by James (9). Or it might inquire into the extent to which the stated objectives of the program are actually being implemented—i.e., the fit between the program's philosophy and its outcomes. Still other kinds of program evaluation might focus on quantifiable changes in patients' clinical status or level of functioning or on patient and/or staff satisfaction with the program's operation. It is for administrators and caregivers in particular programs to determine precisely what questions are important to ask in evaluating programs and how to ask them. This simplest and most specific level of abstraction approaches model programs singly, without reference to or comparison with other programs. In effect, it inquires as to whether a specific program is doing what it has set out to do.

LEVEL II: COMMONALITIES

Another approach assesses model programs comparatively and asks whether there are similarities or commonalities that can be extracted from them for more generalized application. In a recent analysis of diverse model programs selected for their apparent success in meeting the needs of chronic mental patients (5) I concluded that they have certain principles of planning and programming in common. Despite differences in specific locus of care and in control—i.e., whether the program is privately or publicly funded—successful model programs appear to be built on a minimum of eight principles that together form a least common denominator for effective program design for chronic mental patients.

1. Chronic patients targeted. Successful model programs assign top priority to the care of the most severely impaired: they are targeted toward patients who are chronically and persistently ill. If this seems too elementary a principle to merit specific mention, it may be noted that the very failure to assign first priority to chronic patients in many community mental health programs has caused major problems for this population. Zusman and Lamb (10) have contended that although the "basic mission" of deinstitutionalization was originally community-based treatment of chronic patients, "only limited aspects of the original conception have been implemented, while the interest of most workers has gone off in other directions." The result is that community mental health has largely overlooked the chronic patient and has tended instead to focus on those who are "healthy but unhappy." The very existence of chronic mental patients, who are singularly impotent in advocating on their own behalf, has frequently been denied (11, 12). When these patients, with their peculiar combination of service requirements, chronicity, and impotence, have had to compete for scarce resources with others who are less

severely impaired and more socially acceptable, chronic patients have not fared well.

2. *Linkage with other resources.* Realistic linkage with other resources in the community is a second element common to successful model programs for chronic mental patients. This principle is an affirmation of the range and the diversity of treatment needs of those who are chronically ill. In many ways, the planning of relevant deinstitutionalization programs for chronic mental patients is synonymous with planning for human services (11). In addition to psychotherapy, these patients require additional special services that include a "range of living environments and resocialization, vocational rehabilitation, and appropriate work opportunities" (13).

3. *Functional integrity.* Either by itself or in combination with the other resources to which it is linked, a successful model program attempts to provide for its patients the full range of functions that are associated with institutional care. Sociological analyses of the literature reveal that mental hospitals traditionally have fulfilled a variety of functions (14, 15). These include, in addition to long-term comprehensive treatment for disabled individuals, a series of additional functions less readily perceived or acknowledged (e.g., protecting the patient from exploitation or providing him or her with a place of refuge). Much of the difficulty associated with deinstitutionalization efforts may be attributed to the tendency for program planners to overlook, or to neglect to stress, the need for providing out-of-hospital alternatives for the full range of functions performed in hospital settings. Not even the central functions of treatment, asylum, and custody are assured for many deinstitutionalized individuals, not to mention the many peripheral functions. Successful model programs care about the mentally disabled not only as patients but also as social individuals in a complex society. They acknowledge that chronic patients comprise a dependent population for whom the fulfillment of certain basic conditions of human existence must be arranged—conditions that have traditionally, for better or worse, been met within large institutions. These programs are therefore responsive not only to the psychiatric and medical treatment needs of patients but also to their needs for asylum, respite, socialization, and rehabilitation.

4. *Individually tailored treatment.* Model programs that are regarded as successful make a point of providing for their patients personally tailored treatment regimens, whether chemotherapy, psychotherapy, psychosocial rehabilitation, and/or some combination of these and other treatment modalities. This principle of reaching out to patients on an individualized basis necessarily activates certain other elements of treatment that are widely understood as fundamental to the effective care of chronic mental patients. Program elements like 24-hour crisis intervention and case management are automatically assumed and assured when the principle of individualized programming is at work. Individualized programming renders successful model programs the conceptual opposite of "dumping" (indiscriminate and wholesale placement of patients either in hospitals or in the community without consideration for their specific needs).

5. *Cultural relevance and specificity.* Successful model programs are tailored to conform to the local realities of the communities in which they are located. Indeed, the very uniqueness of model programs stands out as one of their underlying similarities. Every model program is a very special event that can be studied and possibly adapted but not precisely duplicated. Because, as Abbott (16) has pointed out, the provision of community-based services for chronic mental patients "has major social components," any successful program for their care "must reflect the character of the community in which the patients are being served."

6. *Specially trained staff.* There is a need in successful model programs for trained staff who are attuned to the unique survival problems of chronic mental patients living in noninstitutional settings. This principle is of such central importance that Polak and Kirby (17) have written that any program lacking staff "who are trained and comfortable working with disturbed patients in community settings . . . is likely to have poorer outcome than psychiatric hospitalization." Special training includes strategies for dealing not only with problems in patient care but also with staff issues, like burnout, that affect role performance.

7. *Hospital liaison.* Successful model programs for chronic mental patients are tied in some manner (and sometimes reluctantly) to a complement of hospital beds. This principle is consistent with the growing view that there are certain patients for whom periods of hospital care continue to be a necessity (11). Irrespective of what specific reasons are considered appropriate for hospitalization—whether for the protection of the patient or of society or whether to provide the patient with diagnostic or intensive treatment services—successful model programs reflect the ever-increasing departure from the polarized antihospital stance that characterized the early years of the deinstitutionalization movement (14, 18, 19).

8. *Internal evaluation.* Descriptions of successful model programs indicate the presence of a kind of ongoing internal assessment mechanism that permits continuous self-monitoring. This kind of evaluation may be something quite apart from formal program evaluation, which tends to be too complex—with too slow a "turnaround" time—to be of use in the kind of equilibrating function that his principle implies. Internal evaluation in these models measures programmatic activities against previously agreed on standards and thus avoids the disjunction among planning, management, and evaluation that tends to characterize evaluative efforts for larger and more complex programs (6). Because model programs are usually relatively

small in size and uncomplicated in structure, they afford unique opportunities for feedback.

In summary, a search for commonalities in model programs that are considered successful demonstrates that there are certain principles that characterize them. The eight principles extracted and discussed here appear to be basic elements in programs that minister effectively to chronic mental patients by acknowledging that they have severe and recurrent problems, that they are often functionally impaired and in need of assistance in gaining access to the most basic of life's entitlements, and, most of all, that their individuality is of greater significance in effective treatment than is any categorical label, such as "schizophrenic," that might be applied to them.

These principles are all concerned with the structural aspects of programming for chronic mental patients and do not extend to program specifics like treatment modalities used or manpower patterns employed. They are simple enough to transcend differences in communities and in demographically distinctive target populations. Indeed, it is apparent that these principles are so simple that they may prove to be disappointing to those who look to model programs to provide instant solutions for their own communities' problems. Moreover, these principles show great similarity not only to the structural properties of effective mental health systems (20, 21) but also to the principles Talbott (22) has put forth as necessities for effective programming in state hospitals of the future. That is noteworthy: it reinforces the notion that the guiding principles of effective planning for chronic patients transcend locational considerations and have more to do with good and humane medical practices than with geography.

Finally, because these principles are structural and are not concerned with the substantive aspects of programming, they can potentially be applied in other setings—i.e., they can be generalized.

LEVEL III: REPRODUCIBILITY AND GENERALIZABILITY

Mental health planners have for some time sought to develop model programs for chronic patients that can be readily reproduced in a variety of settings. Thus Greenblatt and Budson (23), in a descriptive evaluation of five model programs, have asked, "Once demonstration of an effective modality has been made, how do we export it?" In the present context, the critical question is, May we generalize beyond the structural aspects of programming for chronic patients, as described above? It would, of course, be very comforting to be able to point to a laundry list of program specifics and proclaim that if one but includes all of them in a program design, a successful program will be born. Perhaps because the need for solutions to the many problems that plague deinstitutionalization is so acute (14), the assumption is often made that if a model program is proven successful in one place it can be exported to and duplicated in another. The widespread search for reproducible model programs represents a quest for quick-and-easy solutions to alleviate what has often amounted to widespread neglect of chronic mental patients. There is a hope that through identification and diffusion of appropriate models the care of chronic patients will be made more humane.

Unfortunately, there do not appear to be any simple answers. Just as the design of services for chronic patients has too often departed from information derived from "an unwarranted emphasis on the single-episode user of services, a deficiency of interest in people with lifelong disorders, and unwarranted expectations about the effects that programs of general social betterment can have on serious mental illness (24), so have hopes for diffusing model programs been based on the untested assumption that such a process is feasible. Although the structural principles discussed above are generalizable, it is exceedingly difficult—perhaps even dangerous—to attempt to transplant entire programs to alternate settings. Accordingly, those who seek easy answers and choose to view model programs as ready-made solutions for their own communities' problems should proceed with great caution. There are compelling reasons for not attempting to duplicate model programs in other settings.

For one thing, as suggested by the principle of cultural relevance and specificity, any program, model or not, has a cultural context. Abbott (16) has aptly pointed out that "certain models are not applicable to certain communities" and that "a system of care natural to one community may not be appropriate in another because of diverse social, cultural, and political elements." Separation of program specifics from the culture base in which they naturally occur can lead to irrelevant or inappropriate programming. Polak and Kirby (17), in their description of a community-based network of facilities for chronic patients in Denver (a program frequently held up as an extremely successful model) have questioned whether their program is reproducible, and they have specifically speculated about its suitability for rural areas.

No less important a consideration is the fact that many model programs have proceeded with special start-up funds and personnel. Attempts to adapt these programs to the realities of local budgets and resources will inevitably mean cutting out portions of the plan, and it is difficult to foresee the effects of cuts that are made for financial or any other reasons. Test and Stein (25), in discussing the renowned Training in Community Living program in Madison, Wis., have suggested that their own program differs from traditional programs along so many dimensions that it is difficult to sort out "which of the factors carry the greater part of the variance in accounting for the favor-

able results." These authors have said, simply, that beyond such elementary principles as those noted above, we do not know what it is that makes model programs work. Extricating from a complex field of variables a few program specifics has a potential for causing harm.

It is also impossible to know how much of a program's success comes from its having been singled out as a model to be funded and implemented and how much comes from actual program elements. Almost certainly there is a "Hawthorne effect" present in many model programs, a situation in which it becomes difficult to distinguish the positive effects of planned program principles from those which are brought about by "the mere fact of participating in an experiment" (26). Norman Ellis of the University of Alabama, in personal communications to me, has described an unpublished study of profoundly mentally retarded adults, previously considered untrainable, who showed great improvement in self-help, social, and interpersonal skills simply as the result of increased attention from staff. No new program initiatives had been undertaken in this instance, and no new money had been spent, but clinically assessed improvements nevertheless occurred.

An additional limitation on reproducibility comes from precisely how services are delivered and precisely who delivers them in model settings. As Rossi (27) has asserted, "It is difficult to separate the treatment from the manner of delivery." Model programs often attract what Rossi has called "exceptionally devoted persons," so that efficacious results are as likely to come from their ministrations as from the program itself. It is important to realize that the precise method of delivering services to chronic patients is of critical importance in a program's success and that this feature cannot be faithfully reproduced with any degree of certainty.

Finally, it is also important to realize that descriptions of model programs, although "exciting on their own terms," as Mechanic (28) has noted, "have yet to demonstrate that [they] can maintain their early momentum over long periods of time or communicate their enthusiasm to others."

In sum, it appears to be very difficult, if not impossible, to transplant a model program, either in its entirety or in some part, to a new setting. Several factors inhibit such diffusion; these include 1) the difficulty of separating a specific program from its culture base, 2) the difficulty of deciding what program elements are the most important ones to try to duplicate, 3) the danger of interfering with the program's Gestalt, 4) the existence of a "Hawthorne effect" that makes it difficult to assess what changes come from the program itself and what changes derive from the experimental milieu, and 5) the problem of separating program elements from the personnel who execute them.

The limited generalizability of model programs has been noted by Suchman (7), who has suggested that every model is, in effect, the statement of a hypothesis with "almost no generalizability" (p. 79). This is not to say, of course, that models have no values; that is hardly the case. But the value of model programs must be sought in something other than their reproducibility. Beyond the supply of some replicable structural fundamentals, the value of model programs should be sought in their experimental yield.

LEVEL IV: RELEVANCE

The fourth and final level of abstraction in analyzing model programs is, like the first, concerned with evaluation, but with a unique difference. Whereas traditional forms of evaluation look inward to criteria of program success, this kind of evaluation looks outward and uses events in the external world as yardsticks. Such reality testing is of particular importance in mental health planning because it examines the relationship of the model program to the broader scope of mental health service delivery. Since I have been unable to find in the literature a name for this variety of program evaluation, I will call it, for want of a standard term, "impact evaluation" to differentiate it from the better known process and outcome procedures. The difference between impact evaluation and other kinds of program evaluation may be approached metaphorically through the paradox that the operation was a success but the patient died. A given model may be very successful indeed, but does this necessarily mean that deinstitutionalization is "working"? Or does it mean only that a particular model program is working?

Impact evaluation is distinguished by the kinds of questions it poses. While the traditional evaluation might ask, Does this program work? impact evaluation asks, What does this program do to meet the needs of the total population of chronically disabled people? This latter question is one of great importance in view of the fragmented nature of mental health systems. Unless it is asked, a specific program runs the risk of going off into its own orbit with little meaning for the various needs of the population it is intended to serve. In the case of model programs, the question is even more apposite because these experimental endeavors have a strong potential for removing themselves from the mainstream of service delivery problems.

In this context one may ask of model programs, What was the question? If the question is, Do model programs prove that chronic mental patients can be treated successfully in a variety of nontraditional settings? the answer, based on examination of a number of operating programs, must obviously be yes—or, at least, yes, given the presence of certain fundamental program elements. If, however, the question is Can model programs by themselves provide ready solutions for the problems of treating these patients in a

mental health system? the answer must be negative. Beyond their demonstration of some very elementary principles of successful programming, model programs tell us only that individual model programs can work. The inductive leap from this position to the notion that because a given model is successful for a specific target population it can solve the range of problems associated with deinstitutionalization is based on faulty logic: the conclusion does not follow from the evidence at hand. Yet the search for model programs as "answers" to the problems of deinstitutionalization continues. Perhaps this is a natural consequence of the fact that the problems in deinstitutionalization are massive and complex, and the need for quick solutions is felt acutely.

Difficulties in providing services for chronic mental patients have often come from the existence of an "inverse system of care," in which "the most trained and skilled clinicians deal with the most articulate, interesting and likely to succeed clientele," while the existence of those patients most in need is largely ignored (29). Such denial of the most seriously ill exists against a backdrop of diverse planning needs for several subgroups of the total population of chronically ill people, all of whom have different service requirements. In addition to patients released from mental hospitals, planners must consider chronically ill people who are long-time residents of mental hospitals and remain on their rolls, those who are now entering mental hospitals and will become long-stay patients, those who are now entering mental hospitals and will stay for only a short while, and those who are in the community and who, as a direct consequence of deinstitutionalization practices, have never been hospitalized (30).

Each of these demographic subgroups represents, in its own way, fallout from the deinstitutionalization movement. There are problems associated with patient tracking that must be solved so that services can be provided for two rather diametrically different classes of patients who present specific problems for service delivery systems: those who are highly visible as they go again and again through the revolving doors of the service system and those who become virtually invisible when they exit through the doors of mental hospitals and then get lost. The problem of responding to the needs of all the chronically mentally ill affects model programs only indirectly, if at all, but it must be the constant preoccupation of service systems.

To complicate matters even further, it appears that the principles demonstrated to be common to successful model programs may even at time collide head-on with the needs and resources of mental health systems. The very factors that provide high marks for one may give opposite ratings for the other. Thus, for example, improvements in patients' levels of functioning that are directly related to the highly individualized treatment plans and the specially trained staff found in model programs may well meet with a "so what" kind of response in an era of rapid and continuing deinstitutionalization, particularly when "Proposition 13 fever" is rampant. In the face of a nationwide problem of crisis proportions, it is no wonder that model programs which serve only a few patients are viewed by many planners with skepticism.

It must be apparent that model programs provide answers to only some kinds of questions and that these questions are apt to have relatively little to do with the global needs of program planning for chronic mental patients. It would seem then, as suggested earlier, that the appropriate perspective from which to view model programs is for their heuristic possibilities in limited circumstances. In the words of Suchman (7), the model program's value lies precisely in its ability to "indicate the probable success of the planned program, to try out procedures, and to suggest modifications" (p. 140).

MODELS VERSUS SYSTEMS

In summing up the discussion of commonalities above I noted that although it is possible to reach some conclusions about the structural aspects of successful model programs, more specific program practices are not so readily generalizable. There is a reason for this. Questions concerning the "how" of programming for chronic mental patients must be determined largely by such extra-program considerations as timing, available resources, attitudes, and other local conditions. The answers to "how" questions are necessarily highly idiosyncratic.

Understanding these limits on the generalizability of model programs leads, of course, to the question, What is the use of these programs? The answer depends on what is being sought. If one insists on looking at model programs as prototypes for diffusion, he is probably headed for disappointment. If, on the other hand, one alters his perspective and thinks of model programs as hypotheses, not as answers, their value becomes more apparent. Every successful model program may be understood as a hypothesis, as a test for a series of assumptions regarding the effective care of chronic mental patients in a specific setting. Each is an ongoing research effort with evaluative potential.

Model programs have taught us much about the basic ingredients of programs that care, humanely and effectively, for chronic mental patients. Whatever the size, scope, treatment philosophy, affiliation, or location of a particular model program for these patients, a sine qua non of its success appears to be the application of the eight principles outlined above. Understanding these principles throws into bold relief some of the oversights that plague the provision of services to the chronically mentally ill. This is, in itself, a major contribution and a giant step forward; but, beyond this, model programs are not equipped to meet the aggre-

gate demands for services to chronic patients within a defined geographic area. What this means, quite bluntly, is that, to the extent that models and mental health systems are confused, a serious error is made. Major differences exist between mental health systems and model programs, which are important to grasp.

There is, first of all, a difference in the selection of patients to be served in model programs and in mental health systems. Models choose their target populations to conform to their program goals. If patients of a certain age or with a certain institutional history would strain the limits of the experiment's design, those patients need not be admitted to the program. The Soteria model, for example, limits its subjects to unmarried schizophrenic patients between the ages of 16 and 30 who have had more than one hospitalization of brief duration (31). A mental health system does not have the freedom to choose its patients in this way.

Similarly, some models focus on subjects' rehabilitation and exclude custodial or maintenance-level patients who are not considered appropriate candidates for skills training. A mental health system, however, must ultimately face the need to provide for the care of even those who, according to current knowledge, show little hope of successful rehabilitation. A mental health system runs the risk of falling into a seductive trap if it pretends that the needs of all patients can be served through model efforts. Rossi (27) has noted that "a delivery system can simulate success by delivering treatments to individuals who are most likely to recover" or, in the case of chronic mental patients, to exhibit marked and measurable improvement.

The service system, unlike the model program, frequently has difficulty in defining the limits of its task—in identifying precisely what people comprise its target population and how to locate them. Case-finding problems of models are much less complex than the overall epidemiological concerns of mental health systems. In fact, to the extent that there is a class of chronic patients who appear to fit nowhere at all (32), the elevation of model programs to systems solutions has potential for harming rather than helping by diverting attention from the very existence of these patients.

Moreover, model programs and mental health systems are typically accountable to different "masters." Models are primarily responsible for testing and evaluating innovative approaches for the care of those who are chosen for their special programmatic efforts. Mental health systems, however, are most often accountable to governing bodies, like legislatures, for whom mental health services, particularly those targeted toward the care of chronic patients, represent only a portion of their concerns. These bodies are not expected to be experimental in their orientation; they are more concerned with demonstrations of service comprehensiveness and cost effectiveness than with the efficacy of treatment procedures or with the more abstract notion of quality of care.

There are also differences in resource allocation patterns between models and mental health systems. In a model program resource allocation is focused, so that funding, personnel, and material resources are all directed toward patients selected for participation in the program. In a mental health system, however, there is competition for resources among different kinds of patients. There is, indeed, a hierarchy of patient needs in which priorities must be assigned. Miller (29) has cautioned us to "question models that smack of 'triage,' " but the assignment of priorities within a mental health system is essential. The problem is how to make those assignments equitably so that the most seriously ill are not denied services.

Even the kinds of evaluation performed in model programs and in mental health systems differ markedly. Although evaluation efforts of the kind described in the discussion of level I above—assessments of program outcome according to predefined criteria—may be sufficient for model programs, the goals of evaluation in mental health systems must necessarily be much broader and must deal with issues of accountability at a variety of levels (33–37).

To summarize, model programs and mental health systems vary in a number of critical ways. Systems have to serve all in need, not only those who fit in with some predetermined experimental aims. Systems must serve even those who show little hope of improvement. Although model programs can focus their resources on their selected patients, mental health systems have to deal with competition from different kinds of patients, and while mental health systems must account to governing bodies like legislatures, a model program's primary responsibility is to the controlled testing of an innovative approach.

In short, the problems that characterize the delivery of services in mental health systems are numerous and diverse. Model programs do not suffice to provide answers for these problems; they must be dealt with in other ways. Generally too few in number to have widespread effect on the problems of mental health systems and too limited in concept to be reproduced in other settings, model programs remain, in effect, interesting and informative experiments. Although they have been important to the development of principles of programming for chronic mental patients, they do not, in any sense, provide the global answers that are needed to solve the problems of deinstitutionalization.

The differences between the problems that affect model programs and those which affect mental health systems are exemplified in a U.S. General Accounting Office report on the Veterans Administration personal care home program (38), a highly successful model program for foster care placements of chronic patients that is now nearly 30 years old. That report states that, although many more patients qualify for care in personal care homes than are now enrolled in that program, they tend to remain in hospitals for such reasons

as insufficient funds, unavailability of enough suitable community facilities to effect more widespread placements, lack of adequate commitment to the program from the VA system's central office, and patient or family resistance to out-of-hospital placements. Clearly, this is a case where the model program, effective as it is, fails to provide an answer to the problems of the VA system of care.

CONCLUSIONS

This discussion leads logically to several conclusions. First, as Zusman and Lamb (10) have so aptly written, the concept of deinstitutionalization has not yet been given a fair test. The movement has somehow been diverted in community mental health programming from its original purpose so that the complex needs of the most seriously ill have been overlooked. This should not necessarily be construed to mean that most of the chronically mentally ill cannot be treated in community settings some day. It does mean that past errors and oversights—i.e., the confounding variables in deinstitutionalization—must be acknowledged and dealt with so that the problem can be given the cautious and objective evaluation it deserves.

Second, what is derived from model programs depends very much on what questions are asked. There are productive ways to view model programs. One way is to look at the scientific yield of each model's experimental efforts. Another way is to look at several successful models in concert to determine what elements they share. The latter approach yields some structural principles that characterize successful model programs and that are generalizable; they may be applied beyond model settings.

Third, when model programs are stretched in such a way that they are required to provide more than their natural limits permit, they lose some of their value. Planners of mental health services have too often looked to model programs to offer answers that they cannot, by their nature, provide. Specifically, for a variety of sociological and economic reasons, individual model programs cannot, as entities, be successfully generalized to other settings. Beyond the shared structural principles that they so ably demonstrate, their diffusibility is quite limited. If they are to be used in other settings, they must be specifically adapted to these new places. Moreover, there are even substantial risks in adapting these programs, because of difficulties inherent in selecting and extracting particular program elements.

Fourth, it is inappropriate to view model programs as solutions to the problems that mental health systems face. Model programs are too selective in their patient populations and too focused in their designs to be used as systems solutions. Accordingly, it is possible that a point in the testing of models has been reached where these experiments show much of a sameness. Perhaps, in other words, we have reached a plateau, and more model programs have relatively little new information to provide. If this is so, it is time to reassess the value of investing additional scarce resources in the piloting of more and more model programs. The question is no longer whether model programs are valuable and worthwhile—we know that they have been—but, rather, what the magnitude of our future investment in them should be.

The model programs that are pursued in the future should clearly attempt seriously to test new hypotheses—to examine previously untested structural fundamentals with the potential for adding materially to what is already known about the basic principles of effective planning. Unless there is some reason to believe that a new model can do this, it may be wiser to weigh the value of its implementation against the potential benefits to be derived from focusing on service systems.

There is little question that it is important now to direct more energy toward applying some of what is already known to mental health systems. The widespread absence of the eight general principles of effective programming from mental health service systems is glaringly evident. How, then, may the knowledge derived from existing models be applied to planning within mental health systems? What are the best ways to convert the structural principles of model programs into viable service system elements? How may mental health systems apply those principles in the face of the special problems imposed by their need to establish priorities for resource allocation? How may the program evaluation efforts of mental health systems be redesigned to yield assessments of those program principles while they also address the systems' special needs for accountability?

It seems that these are relevant questions for the 1980s. Although the literature is now beginning to focus more intensively on the problems of mental health systems and their solutions, there is a real need to develop strategies for translating model-derived knowledge into systems-related action. It will take fundamental changes in attitudes and funding practices to shift from the habit of looking to models as solutions toward integrating what is already known from them into service delivery practices. But a continuing failure to place model programs in perspective will only divert attention from the more global needs of the population of chronically mentally ill people and will prolong the serious problems that are now, unfortunately, widely identified with the deinstitutionalization movement.

The Use of ECT in the Treatment of Schizophrenia

BY CARL SALZMAN, M.D.

ECT has been replaced by neuroleptics for the treatment of schizophrenia. The production of serious drug-related side effects, particularly tardive dyskinesia, raises the question of the efficacy and toxicity of ECT versus neuroleptics. Most of the studies in the English literature on the use of ECT in the treatment of schizophrenia are unacceptable according to contemporary criteria; the question of ECT versus neuroleptic drugs thus remains unanswered. In the few acceptable published studies, clinical response to ECT was inversely proportional to duration of schizophrenic symptoms. Schizophrenic patients with affective and catatonic symptoms responded best; those with chronic symptoms rarely responded. ECT does not alter the fundamental psychopathology of schizophrenia.

Electrically induced convulsions, administered by Cerletti and Bini in 1938 to a catatonic schizophrenic patient, introduced ECT into clinical psychiatry (1). ECT was a modification of chemically induced seizures. It was based on an earlier erroneous belief that schizophrenia and epilepsy could not coexist in the same patient as well as the observation that patients with psychotic symptoms sometimes improved after spontaneous or accidentally induced seizures (2). It was reasoned that the induction of epileptic-like seizures, either chemically or electrically, would thus be an effective treatment for schizophrenia.

USE OF ECT BEFORE THE INTRODUCTION OF NEUROLEPTICS

One of the earliest and most repeated observations was the favorable response to ECT of acutely ill schizophrenic patients compared with those who had a long and chronic illness. Most authors defined acute illness as one year or less of symptoms. Those who had been ill less than 6 months had the best response of all, whereas patients who were ill more than 2 years showed very poor response (3, 4). Early studies of ECT with schizophrenic patients also emphasized the symptomatic improvement achieved with this treatment even if hospital discharge was not attained. This improvement, seen in acutely ill as well as agitated patients, led to a dramatic decrease in the use of barbiturates, restraints, wet packs, and isolation (5). Patients with catatonic or affective symptoms responded particularly well to ECT (5, 6). In an early paper Pacella and Barrera (7) commented that patients who improved "almost always had strong affective components of depression, guilt, worthlessness, hopelessness, self-condemnation and suicidal tendencies." However, there was considerable disagreement among authors about the role of ECT with the paranoid patient. The earliest follow-up studies of successfully treated patients with acute schizophrenia suggested a low relapse rate. However, subsequent follow-up studies reported relapse rates as high as 83% (8). These follow-up studies led to the conclusion that ECT was useful primarily for patients who had a favorable prognosis and who would have recovered with other treatments or with no treatments (9). The results of ECT with patients who were chronically ill with schizophrenia and who had a poor prognosis were uniformly discouraging.

Early Studies

In the early reports of ECT efficacy in schizophrenia, diagnosis of schizophrenic patients was by clinical judgment rather than by adherence to rigorous diagnostic criteria. Similarly, the standards for remission, recovery, or improvement often were not specified or were made by clinical judgment and thus varied from report to report. The number of treatments also varied greatly from study to study, and control groups were rare. Nevertheless, the results of these early clinical reports were similar enough to draw general inferences regarding the role of ECT in the treatment of schizophrenia. A number of these observations are still valid today, despite more rigorous and sophisticated clinical and experimental methodology.

1. ECT offers symptomatic relief for acutely ill patients. Social and self-care behavior improve, and hospital discharge rates increase.
2. The shorter the duration of illness, the better the

Presented at a conference of the National Institute of Mental Health in New Orleans, La., Feb. 22–25, 1978. Received Sept. 10, 1979; revised Jan. 30, 1980; accepted March 7, 1980.

outcome with ECT. Patients who have been ill less than one year do much better than patients ill more than one year.

3. Acutely ill patients with catatonic or affective symptoms respond best.

4. Chronic, deteriorated patients and patients who have been symptomatic for more than 2 years have a poor response to ECT.

5. Relapse rates are high for all patients who improve. As the duration of illness lengthens, the probability of relapse increases.

ECT IN THE ERA OF NEUROLEPTICS

Studies of ECT Without Drug Comparisons

Lehmann (10) introduced the replacement of ECT by neuroleptics as a treatment for schizophrenia. He reported that "the time required for full recovery (with chlorpromazine) is shorter than with electroconvulsive treatment, and furthermore, the patient's insight is often better because awareness and confusion do not develop under treatment." Drugs soon replaced ECT for the treatment of schizophrenia in hospitals throughout the world. Nevertheless, studies of ECT in schizophrenia continued. Small and associates (11) reported an overall patient discharge rate of nearly 30% at 60–90 days after ECT or fluorothyl convulsive treatment. This rate was lower than many of those reported in the early years of ECT treatment. Doongaji and associates reported a 50% reduction in symptoms (12) in acutely ill schizophrenic patients, but after 3 months only 21 of the 46 patients available for follow-up had sustained their improvement.

Wells (13) reported a 10-year survey of ECT in the treatment of nonchronic schizophrenic patients who had not responded to phenothiazines. A total of 276 patients received an average of seven treatments, and 75% were thought to have a decrease in symptoms; catatonic and schizoaffective patients did best. However, 2 years later 46% of the 95 patients available for follow-up had relapsed. Wells concluded that only patients suffering from a first episode of schizophrenia that included depressive symptoms were good ECT responders. In a retrospective survey of 118 consecutively admitted patients, Folstein and associates (14) found that good response to ECT was predicted by the presence of affective disorder. These factors predicted good therapeutic outcome regardless of whether the patient was also diagnosed as schizophrenic. In contrast, patients who had only Schneiderian first-rank symptoms for schizophrenia did not improve with ECT. Dempsey and associates (15) presented the favorable outcome of 5 acute schizophrenic patients with a history of drug abuse. These patients were initially diagnosed as schizoaffective and failed to respond to phenothiazines, but all responded well to a course of eight sessions of ECT followed by maintenance lithium carbonate therapy. In addition to these studies, reports by other experienced clinicians have been enthusiastic about the role of ECT as the primary treatment for acute schizophrenia (16–19).

In addition to the many recent studies of ECT efficacy in acute schizophrenia, several reports have found ECT to be useless in chronic schizophrenic patients (20). Although symptoms of agitation and depression are diminished by ECT (21), behavioral and affective improvement is not lasting (22).
